## About the Editors

## Antonio Bianchi

Antonio Bianchi received his Ph.D. in Chemistry at University of Florence in Italy in 1989. He was employed by the same university first as a tenured Researcher, then as an Associate Professor, and from 2000 as Professor of General and Inorganic Chemistry. From 2006 to 2009 he served as the Head of the Department of Chemistry "Ugo Schiff" of the said university. His divers research interests encompass inorganic chemistry, supramolecular chemistry, coordination of anions, thermodynamics of coordination compounds, catalysis and green energy production.

## Matteo Savastano

Matteo Savastano received his Ph.D. in chemical sciences (inorganic and supramolecular chemistry) in 2018, from the University of Florence, Italy, under the supervision of Prof. Antonio Bianchi. After stays at the University of Jaén (Spain) and at the University of Valencia (Spain), he remained as a postdoctoral research fellow at the Department of Chemistry "Ugo Schiff" in Florence for five more years. In 2023 he moved to the San Raffaele University, based in Rome, Italy, where he currently is associate professor of general and inorganic chemistry. His main interests are anion and cation coordination chemistry, supramolecular interactions, solution equilibria, crystal structures and polyiodides.

#### Abstract

The phenyltetrel pyridine-2-olates $\mathrm{Ph} E(\mathrm{pyO})_{3}(E=\mathrm{Si}, \mathrm{Ge}, \mathrm{Sn} ; \mathrm{pyO}=$ pyridine-2-olate $)$ were synthesized from the respective chlorides $\mathrm{Ph} E C l_{3}$ and 2-hydroxypyridine (2-pyridone) with the aid of a sacrificial base (triethylamine). Their solid-state structures were determined by single-crystal X-ray diffraction. $\mathrm{PhSi}(\mathrm{pyO})_{3}$ exhibits a three-fold capped tetrahedral Si coordination sphere ([4+3]coordination, $\mathrm{Si} \cdots \mathrm{N}$ separations ca. $3.0 \AA$ ), in accordance with structures of previously reported silicon pyridine-2-olates. $\mathrm{PhGe}(\mathrm{pyO})_{3}$ adopts a related [4+3]-coordination mode, which differs in terms of the tetrahedral faces capped by the pyridine N atoms. Additionally, shorter $\mathrm{Ge} \cdots \mathrm{N}$ separations (2.8-2.9 $\AA$ ) indicate a trend toward tetrel hypercoordination. $\mathrm{PhSn}(\mathrm{pyO})_{3}$ features heptacoordinate tin within a pentagonal bipyramidal Sn coordination sphere ( $\mathrm{Sn} \cdots \mathrm{N}$ separations $2.2-2.4 \AA$ ). For the Si and Sn compounds, ${ }^{29} \mathrm{Si}$ and ${ }^{119} \mathrm{Sn}$ NMR spectroscopy indicates retention of their tetrel coordination number in chloroform solution.

Keywords: 2-hydroxypyridine; hypercoordination; ${ }^{119} \mathrm{Sn}$ solid-state NMR; tetrel; X-ray diffraction

## 1. Introduction

In previous studies [1-3] it was shown that in silicon pyridine-2-olates the potentially bidentate pyO group ( $\mathrm{pyO}=$ pyridine-2-olate) is essentially monodentate, bound to Si through an $\mathrm{Si}-\mathrm{O}$ bond and capping tetrahedral faces of the Si coordination sphere by rather remote $\mathrm{N} \cdots$ Si coordination (e.g., in compounds I [2] and II [3], Figure 1). In addition, it has been shown that pyridine-2-olates may serve as bridging ligands with their N atom coordinating to a transition metal (TM) atom, thus fostering the formation of heteronuclear $\mathrm{Si} \cdots \mathrm{TM}$ complexes with higher-coordinate Si atom, for example in compounds III and IV [2] and some others [2,4]. Whereas in pyO-TM-silyl-complexes with tetracoordinate Si atom and thus formally covalent TM-Si bond (such as V [5] and VI [6]) pyO ligand(s) may buttress this diatomic core and thus simply add some stability, in cases with formally dative bonding or weak $\mathrm{TM} \cdots \mathrm{Si}$ attraction the availability of dangling N -donor sites in silicon pyridine-2-olates may be a key toward their binding to transition metals. With the perspective of extending studies of pyO-bridged TM-tetrel-complexes to heavier congeners of Si , the mode(s) of pyO-coordination at the heavier congeners ( $\mathrm{Ge}, \mathrm{Sn}$ ) may hint at their suitability as starting materials for pyO-bridged tetrel-TM complexes. So far, molecular structures (in terms of crystallographically proven configurations) of germanium pyridine-2-olates are unknown [7]. For Sn-pyO-compounds, two crystal structures have been reported for compounds with penta- [8] or penta- and hexacoordinate Sn [9] in which the pyridine-2-olate is bridging two Sn atoms (with $\mathrm{Sn}-\mathrm{O}$ and $\mathrm{Sn}-\mathrm{N}$ bonds). These examples, however, involve a distannamethane motif [8] or a combination of different Sn sites ( $\mathrm{SnBu}_{2}$ and $\mathrm{SnBu}_{3}$ groups) [9]. Crystallographic studies of pyO coordination in rather simple organotin compounds are yet to be performed. In the current study, we present a systematic comparison of the solid-state structures of the series of related phenyltetrel
compounds $\mathrm{Ph} E(\mathrm{pyO})_{3}(E=\mathrm{Si}, \mathrm{Ge}, \mathrm{Sn})$. Whereas our interest in these compounds mainly arises from aspects of coordination chemistry (coordination of bidentate ligands at the tetrel and as bridging ligands between tetrel and transition metal), the exploration of coordination compounds of heavier tetrels with pyridine bases may also be of interest for other research fields. Both pyridine bases as ligands $[10,11]$ and tin as a central atom [12] are the focus of the development of anti-cancer drugs.

## 2. Materials and Methods

### 2.1. General Considerations

Starting materials 2-hydroxypyridine (ABCR, Karlsruhe, Germany, 98\%), phenyltrichlorosilane (Wacker, Burghausen, Germany), phenyltrichlorogermane (Gelest, Tullytown, PA, USA, 95\%) and phenyltrichlorostannane (Sigma-Aldrich, Steinheim, Germany, $98 \%$ ) were used as received without further purification. THF, diethyl ether, and triethylamine were distilled from sodium/benzophenone and kept under argon atmosphere. Chloroform, stabilized with amylenes (Honeywell, Seelze, Germany, $\geq 99.5 \%$ ) and $\mathrm{CDCl}_{3}$ (Deutero, Kastellaun, Germany, $99.8 \%$ ) were stored over activated molecular sieves ( $3 \AA$ ) for at least 7 days and used without further purification. All reactions were carried out under an atmosphere of dry argon utilizing standard Schlenk techniques. Solution NMR spectra $\left({ }^{1} \mathrm{H},{ }^{13} \mathrm{C},{ }^{29} \mathrm{Si},{ }^{119} \mathrm{Sn}\right)$ (cf. Figures S1-S9 in the supporting information) were recorded on Bruker Avance III 500 MHz and Bruker Nanobay 400 MHz spectrometers. ${ }^{1} \mathrm{H},{ }^{13} \mathrm{C}$ and ${ }^{29} \mathrm{Si}$ chemical shifts are reported relative to $\mathrm{Me}_{4} \mathrm{Si}(0 \mathrm{ppm})$ as internal reference. ${ }^{119} \mathrm{Sn}$ chemical shifts are reported relative to $\mathrm{Me}_{4} \mathrm{Sn}(0 \mathrm{ppm})$ with external referencing. ${ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}$ NMR signals were assigned in accord with mutual coupling patterns (in case of ${ }^{1} \mathrm{H}$ ) and according to the shifts of corresponding ${ }^{1} \mathrm{H}$ or ${ }^{13} \mathrm{C}$ NMR signals in related compounds $\mathrm{MeSi}(\mathrm{pyO})_{3}$ [2], $\mathrm{Ph}_{2} \mathrm{Si}(\mathrm{pyO})_{2}$ [3] and $\mathrm{PhP}(\mathrm{pyO})_{2}$ [13]. Furthermore, ${ }^{1} \mathrm{H}-{ }^{13} \mathrm{C}$ HSQC techniques were employed for ${ }^{13} \mathrm{C}$ NMR signal assignment of compound $\mathrm{PhSn}(\mathrm{pyO})_{3}$. The ${ }^{119}$ Sn MAS NMR spectrum of $\mathrm{PhSn}(\mathrm{pyO})_{3}$ was recorded on a Bruker Avance 400 WB spectrometer using a 4 mm zirconia $\left(\mathrm{ZrO}_{2}\right)$ rotor and an MAS frequency of $v_{\text {spin }}=13 \mathrm{kHz}$. The
chemical shift is reported relative to $\mathrm{Me}_{4} \mathrm{Sn}(0 \mathrm{ppm})$ and was referenced with the aid of a sample of $\mathrm{SnO}_{2}\left(\delta_{\text {iso }}=-603 \mathrm{ppm}\right)$. Determination of the chemical shift anisotropy (CSA) tensor principal components from the spinning sideband spectrum was carried out with the SOLA module contained in the Bruker software package TOPSPIN. Principal components $\delta_{11}, \delta_{22}, \delta_{33}$ as well as span $\Omega$ and skew $\kappa$ are reported according to the Herzfeld-Berger notation $[14,15]$. Elemental analyses were performed on an Elementar Vario MICRO cube For single-crystal X-ray diffraction analyses, crystals were selected under an inert oil and mounted on a glass capillary (which was coated with silicone grease). Diffraction data were collected on a Stoe IPDS-2/2T diffractometer (STOE, Darmstadt, Germany) using Mo $K \alpha$-radiation. Data integration and absorption correction were performed with the STOE software XArea and XShape, respectively. The structures were solved by direct methods using SHELXS-97 or SHELXT and refined with the full-matrix least-squares methods of $F^{2}$ against all reflections with SHELXL-2014/7 [16-19]. All non-hydrogen atoms were anisotropically refined, and hydrogen atoms were isotropically refined in idealized position (riding model). For details of data collection and refinement (incl. the use of SQUEEZE in the refinement of the structure of $\left.\mathrm{PhSi}(\mathrm{pyO})_{3} \cdot \mathrm{THF}\right)$ see Appendix A, Table A1. Graphics of molecular structures were generated with ORTEP-3 [20,21] and POV-Ray 3.7 [22]. CCDC $2217508\left(\mathrm{PhSi}(\mathrm{pyO})_{3} \cdot \mathrm{THF}\right), 2217510\left(\mathrm{PhSi}(\mathrm{pyO})_{3} \cdot \mathrm{CHCl}_{3}\right), 2217509\left(\mathrm{PhGe}(\mathrm{pyO})_{3}\right)$, and $2217511\left(\mathrm{PhSn}(\mathrm{pyO})_{3}\right)$ contain the supplementary crystal data for this article. These data can be obtained free of charge from the Cambridge Crystallographic Data Centre via https://www.ccdc.cam.ac.uk/structures/ (accessed on 4 November 2022).

### 2.2. Syntheses and Characterization

Compound $\mathrm{PhSi}(\mathrm{pyO})_{3} \cdot \operatorname{THF}\left(\mathrm{C}_{25} \mathrm{H}_{25} \mathrm{~N}_{3} \mathrm{O}_{4} \mathrm{Si}\right)$. A Schlenk flask was charged with magnetic stirring bar and 2-hydroxypyridine ( $2.00 \mathrm{~g}, 20.8 \mathrm{mmol}$ ), then evacuated and set under Ar atmosphere prior to adding THF ( 70 mL ) and triethylamine ( $2.50 \mathrm{~g}, 24.7 \mathrm{mmol}$ ). The resultant mixture was stirred at room temperature, and phenyltrichlorosilane ( 1.60 g , 7.56 mmol ) was added dropwise via syringe through a septum. Upon completed addition of silane, stirring was continued for 30 min , whereupon the flask was stored at $5^{\circ} \mathrm{C}$ overnight. Thereafter, the triethylamine hydrochloride precipitate was removed by filtration and washed with THF ( $2 \times 5 \mathrm{~mL}$ ). From the combined filtrate and washings, the solvent was removed under reduced pressure (condensation into a cold trap) to afford a colorless solid. This crude product was dissolved into hot THF ( 4 mL ) and allowed to crystallize upon cooling to room temperature. From this coarse crystalline product (thick colorless needles) of $\mathrm{PhSi}(\mathrm{pyO})_{3} \ldots$ THF the supernatant was removed by decantation; the crystals were washed with THF $(2 \times 5 \mathrm{~mL})$ and briefly dried in vacuum. Yield: $2.29 \mathrm{~g}(4.98 \mathrm{mmol}$, $66 \%)$. The yield is reported with respect to the composition $\mathrm{PhSi}(\mathrm{pyO})_{3} \cdots \mathrm{THF}$, which is in accord with the composition of a single crystal taken from the freshly crystallized product for single-crystal X-ray diffraction analysis. ${ }^{1}$ H NMR spectroscopy (cf. Figure S1 in the supporting information) already indicates some loss of THF upon drying. This effect was also found with elemental analysis: elemental analysis for $\mathrm{C}_{21} \mathrm{H}_{17} \mathrm{~N}_{3} \mathrm{O}_{3} \mathrm{Si} \cdots 0.5$ THF (423.52 g. $\mathrm{mol}^{-1}$ ): C, $65.23 \%$; H, $5.00 \%$; N, $9.92 \%$; found C, $65.21 \% ; \mathrm{H}, 5.10 \% ; \mathrm{N}, 9.96 \% .{ }^{1} \mathrm{H}$ NMR ( $\mathrm{CDCl}_{3}$ ): $\delta(\mathrm{ppm}) 8.11-8.07(\mathrm{~m}, 2 \mathrm{H}, \mathrm{Ph}-\mathrm{o}), 8.01\left(\mathrm{~m}, \mathrm{br}, 3 \mathrm{H}, \mathrm{H}^{6}\right), 7.52\left(\mathrm{~m}, \mathrm{br}, 3 \mathrm{H}, \mathrm{H}^{4}\right)$, 7.44-7.32 (m, 3H, Ph-m/p), 6.92 (d, br, 3H, $8.2 \mathrm{~Hz}, \mathrm{H}^{3}$ ), $6.82\left(\mathrm{~m}, \mathrm{br}, 3 \mathrm{H}, \mathrm{H}^{5}\right) ;{ }^{13} \mathrm{C}\left\{{ }^{1} \mathrm{H}\right\}$ NMR $\left(\mathrm{CDCl}_{3}\right): \delta(\mathrm{ppm}) 160.3\left(\mathrm{C}^{2}\right), 147.3\left(\mathrm{C}^{6}\right), 139.1\left(\mathrm{C}^{4}\right), 135.6(\mathrm{Ph}-\mathrm{o}), 130.9(\mathrm{Ph}-\mathrm{p}), 129.0(\mathrm{Ph}-\mathrm{i})$, $127.6(\mathrm{Ph}-\mathrm{m}), 118.2\left(\mathrm{C}^{5}\right), 113.0\left(\mathrm{C}^{3}\right) ;{ }^{29} \mathrm{Si}\left\{{ }^{1} \mathrm{H}\right\}$ NMR $\left(\mathrm{CDCl}_{3}\right): \delta(\mathrm{ppm})-64.7$.

Some crystals of the chloroform solvate $\mathrm{PhSi}(\mathrm{pyO})_{3} \cdot \mathrm{CHCl}_{3}\left(\mathrm{C}_{22} \mathrm{H}_{18} \mathrm{Cl}_{3} \mathrm{~N}_{3} \mathrm{O}_{3} \mathrm{Si}\right)$ were obtained by recrystallization of the THF solvate in chloroform.

Compound $\mathrm{PhGe}(\mathrm{pyO})_{3}\left(\mathrm{C}_{21} \mathrm{H}_{17} \mathrm{GeN}_{3} \mathrm{O}_{3}\right)$. A Schlenk flask was charged with magnetic stirring bar and 2-hydroxypyridine ( $0.25 \mathrm{~g}, 2.63 \mathrm{mmol}$ ), then evacuated and set under Ar atmosphere prior to adding THF ( 5 mL ) and triethylamine ( $0.40 \mathrm{~g}, 3.96 \mathrm{mmol}$ ). The resultant mixture was stirred at room temperature, and phenyltrichlorogermane ( $0.25 \mathrm{~g}, 0.97 \mathrm{mmol}$ ) was added dropwise via syringe through a septum. Upon completion, addition of the germane, a thick suspension was obtained. Therefore, further THF ( 2 mL ) was added with
stirring, before the flask was stored at $5{ }^{\circ} \mathrm{C}$ for five days. Thereafter, the triethylamine hydrochloride precipitate was removed by filtration and washed with THF ( 3 mL ). From the combined filtrate and washings, the solvent was removed under reduced pressure (condensation into a cold trap) to afford a viscous oily residue. This crude product was dissolved into THF $(0.5 \mathrm{~mL})$, then diethyl ether $(1 \mathrm{~mL})$ was added at room temperature, and the solution was stored undisturbed at room temperature for crystallization to commence. In the course of some days, crystals of $\mathrm{PhGe}(\mathrm{pyO})_{3}$ formed. For enhanced yield, the flask was stored at $-24^{\circ} \mathrm{C}$ overnight prior to isolation of the product, which was achieved by decantation of the supernatant, washing with diethyl ether ( 1 mL ), and drying in vacuum. Yield: $0.26 \mathrm{~g}(0.60 \mathrm{mmol}, 68 \%)$. A single crystal was taken from this product for singlecrystal X-ray diffraction analysis. Elemental analysis for $\mathrm{C}_{21} \mathrm{H}_{17} \mathrm{GeN}_{3} \mathrm{O}_{3}\left(431.99 \mathrm{~g} \cdot \mathrm{~mol}^{-1}\right)$ : C, $58.39 \% ; \mathrm{H}, 3.97 \%$; N, $9.73 \%$; found C, $58.23 \% ; \mathrm{H}, 4.38 \% ; \mathrm{N}, 9.79 \% .{ }^{1} \mathrm{H}$ NMR $\left(\mathrm{CDCl}_{3}\right): \delta$ (ppm) 8.13-8.09 (m, 2H, Ph-o), $7.86\left(\mathrm{~m}, 3 \mathrm{H}, \mathrm{H}^{6}\right), 7.49\left(\mathrm{~m}, 3 \mathrm{H}, \mathrm{H}^{4}\right), 7.44-7.34(\mathrm{~m}, 3 \mathrm{H}, \mathrm{Ph}-\mathrm{m} / \mathrm{p})$, $6.80\left(\mathrm{~d}, 3 \mathrm{H}, 8.3 \mathrm{~Hz}, \mathrm{H}^{3}\right), 6.70\left(\mathrm{~m}, 3 \mathrm{H}, \mathrm{H}^{5}\right) ;{ }^{13} \mathrm{C}\left\{{ }^{1} \mathrm{H}\right\} \mathrm{NMR}\left(\mathrm{CDCl}_{3}\right): \delta(\mathrm{ppm}) 163.3\left(\mathrm{C}^{2}\right), 145.9$ $\left(\mathrm{C}^{6}\right)$, $139.5\left(\mathrm{C}^{4}\right), 134.3$ (Ph-o), $133.8(\mathrm{Ph}-\mathrm{i}), 130.8(\mathrm{Ph}-\mathrm{p}), 128.2(\mathrm{Ph}-\mathrm{m}), 116.2\left(\mathrm{C}^{5}\right), 111.7\left(\mathrm{C}^{3}\right)$.

Compound $\mathrm{PhSn}(\mathrm{pyO})_{3}\left(\mathrm{C}_{21} \mathrm{H}_{17} \mathrm{~N}_{3} \mathrm{O}_{3} \mathrm{Sn}\right)$. A Schlenk flask was charged with magnetic stirring bar and 2-hydroxypyridine ( $2.03 \mathrm{~g}, 21.4 \mathrm{mmol}$ ), then evacuated and set under Ar atmosphere prior to adding THF $(40 \mathrm{~mL})$ and triethylamine $(2.66 \mathrm{~g}, 26.3 \mathrm{mmol})$. The resultant mixture was stirred in an ice/ethanol bath (ca. $-10^{\circ} \mathrm{C}$ ), and phenyltrichlorostannane $(2.18 \mathrm{~g}, 7.21 \mathrm{mmol})$ was added dropwise via syringe through a septum. Upon completed addition of the stannane, the mixture was stored at $5^{\circ} \mathrm{C}$ for five days, whereupon the triethylamine hydrochloride precipitate was removed by filtration and washed with THF $(10 \mathrm{~mL})$. From the combined filtrate and washings, the solvent was removed under reduced pressure (condensation into a cold trap) to afford a white solid residue. This crude product was recrystallized from hot THF. The colorless solid product thus obtained was filtered off, washed with THF ( 2 mL ) and dried in vacuum. Yield: $2.13 \mathrm{~g}(4.46 \mathrm{mmol}, 63 \%)$. A single crystal was taken from this product for single-crystal X-ray diffraction analysis. Elemental analysis for $\mathrm{C}_{21} \mathrm{H}_{17} \mathrm{~N}_{3} \mathrm{O}_{3} \mathrm{Sn}\left(478.09 \mathrm{~g} \cdot \mathrm{~mol}^{-1}\right)$ : $\mathrm{C}, 52.76 \%$; $\mathrm{H}, 3.58 \%$; $\mathrm{N}, 8.79 \%$; found C , $52.64 \% ; \mathrm{H}, 3.67 \%$; N, $8.73 \%$. ${ }^{1} \mathrm{H}$ NMR $\left(\mathrm{CDCl}_{3}\right): \delta(\mathrm{ppm}) 7.71-7.62\left(\mathrm{~m}, 5 \mathrm{H}, \mathrm{Ph}-\mathrm{o}, \mathrm{H}^{6}\right), 7.57$ $\left(\mathrm{m}, 3 \mathrm{H}, \mathrm{H}^{4}\right), 7.33-7.29(\mathrm{~m}, 3 \mathrm{H}, \mathrm{Ph}-\mathrm{m} / \mathrm{p}), 6.68\left(\mathrm{~d}, 3 \mathrm{H}, 8.4 \mathrm{~Hz}, \mathrm{H}^{3}\right), 6.58\left(\mathrm{~m}, 3 \mathrm{H}, \mathrm{H}^{5}\right) ;{ }^{13} \mathrm{C}\left\{{ }^{1} \mathrm{H}\right\}$ NMR ( $\mathrm{CDCl}_{3}$ ): $\delta(\mathrm{ppm}) 167.0\left(22 \mathrm{~Hz}, \mathrm{C}^{2}\right), 145.6(1451 \mathrm{~Hz}, 1386 \mathrm{~Hz}, \mathrm{Ph}-\mathrm{i}), 142.3\left(\mathrm{C}^{6}\right), 141.8$ ( $18 \mathrm{~Hz}, \mathrm{C}^{4}$ ), 133.7 ( $77 \mathrm{~Hz}, \mathrm{Ph}-\mathrm{o}$ ), 129.5 ( $25 \mathrm{~Hz}, \mathrm{Ph}-\mathrm{p}$ ), 128.6 ( $128 \mathrm{~Hz}, 122 \mathrm{~Hz}, \mathrm{Ph}-\mathrm{m}$ ), 112.5 $\left(\mathrm{C}^{5}\right)$, $111.3\left(36 \mathrm{~Hz}, \mathrm{C}^{3}\right) ;{ }^{119} \mathrm{Sn}\left\{{ }^{1} \mathrm{H}\right\}$ NMR $\left(\mathrm{CDCl}_{3}\right): \delta(\mathrm{ppm})-609 ;{ }^{119} \mathrm{Sn} \mathrm{CP} / \mathrm{MAS}$ NMR: $\delta_{\text {iso }}(\mathrm{ppm})-617$.

Note: For some ${ }^{13} \mathrm{C}$ signals we observed ${ }^{117 / 119} \mathrm{Sn}$ satellites, the ${ }^{117} \mathrm{Sn}$ and ${ }^{119} \mathrm{Sn}$ contributions of which are not resolved. Therefore, the average $J\left({ }^{117 / 119} \mathrm{Sn}-{ }^{13} \mathrm{C}\right)$ coupling constants are given in parentheses for those signals where applicable. For the pair of $\mathrm{Ph}-\mathrm{o}$ and Ph-m ${ }^{13} \mathrm{C}$ NMR signals (at 133.7 and 128.6 ppm ) the larger $J\left({ }^{117 / 119} \mathrm{Sn}-{ }^{13} \mathrm{C}\right.$ ) coupling is observed for the signal at 128.6 ppm . The assignment to o - and m-position is in accord with ${ }^{13} \mathrm{C}$ NMR data of other phenyltin compounds, e.g., $\mathrm{PhSn}\left(E \mathrm{SiMe}_{2}\right)_{3} \mathrm{SiMe}(\mathrm{E}=\mathrm{S}, \mathrm{Se}, \mathrm{Te})$, which give rise to signals of $\mathrm{Ph}-\mathrm{o}$ and $\mathrm{Ph}-\mathrm{m}$ carbon atoms around $134-135 \mathrm{ppm}$ and $128-$ 129 ppm , respectively [23], and for $\mathrm{Me}_{3} \mathrm{SnPh}$ the same phenomenon of ${ }^{3} \mathrm{~J}(\mathrm{SnC})>{ }^{2} \mathrm{~J}(\mathrm{SnC})$ has been reported [24].

## 3. Results and Discussion

### 3.1. Crystallographic Analysis of the Molecular Structures of $\operatorname{PhE}(p y O)_{3}(E=S i, G e, S n)$

Compounds $\mathrm{Ph} E(\mathrm{pyO})_{3}(E=\mathrm{Si}, \mathrm{Ge}, \mathrm{Sn})$ were synthesized from the respective chlorides PhECl 3 and 2-hydroxypyridine in THF with the aid of triethylamine as a sacrificial base (Scheme 1). In all cases, the crystalline products obtained were of sufficient quality for single-crystal X-ray diffraction analysis (Table A1). The crystallographically determined molecular structures of $\mathrm{Ph} E(\mathrm{pyO})_{3}(E=\mathrm{Si}, \mathrm{Ge}, \mathrm{Sn})$ are shown in Figure 2 and selected interatomic separations and bond angles are given in Table 1. Whereas the Ge- and Sncompound crystallized from THF without including solvent of crystallization, compound $\mathrm{PhSi}(\mathrm{pyO})_{3}$ crystallized as a THF solvate $\mathrm{PhSi}(\mathrm{pyO})_{3} \cdots$ THF with severely disordered sol-
vent. Recrystallization from chloroform afforded an isomorphous solvate $\mathrm{PhSi}(\mathrm{pyO})_{3}$. $\mathrm{CHCl}_{3}$, the disordered solvent of which could be refined in a satisfactory manner. As the structure models of $\mathrm{PhSi}(\mathrm{pyO})_{3}$ in the two solvates are of similar quality, and the molecular conformation of the silane in those structures is the same, the data from the solvate $\mathrm{PhSi}(\mathrm{pyO})_{3} \cdot \mathrm{CHCl}_{3}$ will be used in the further discussion as a representative example.

Scheme 1. Generic scheme of the syntheses of compounds $\mathrm{PhSi}(\mathrm{pyO})_{3}, \mathrm{PhGe}(\mathrm{pyO})_{3}$, and $\mathrm{PhSn}(\mathrm{pyO})_{3}$. The reactions were performed at room temperature for $\mathrm{PhSi}(\mathrm{pyO})_{3}$ and $\mathrm{PhGe}(\mathrm{pyO})_{3}$ and at $-10^{\circ} \mathrm{C}$ for $\mathrm{PhSn}(\mathrm{pyO})_{3}$.

Figure 2. Molecular structures of (a) $\mathrm{PhSi}(\mathrm{pyO})_{3}$ (in the crystal structure of the solvate $\left.\mathrm{PhSi}(\mathrm{pyO})_{3} \cdot \mathrm{CHCl}_{3}\right)$, (b) $\mathrm{PhGe}(\mathrm{pyO})_{3}$, and (c) $\mathrm{PhSn}(\mathrm{pyO})_{3}$ with thermal displacement ellipsoids at the $50 \%$ probability level and labels of selected non-hydrogen atoms. Selected interatomic distances ( A ) and angles are listed in Table 1.

Table 1. Selected interatomic separations $[\AA]$ and bond angles [deg] in the tetrel $(E=\mathrm{Si}, \mathrm{Ge}, \mathrm{Sn})$ coordination spheres of $\mathrm{PhSi}(\mathrm{pyO})_{3}, \mathrm{PhGe}(\mathrm{pyO})_{3}$ and $\mathrm{PhSn}(\mathrm{pyO})_{3}$ and their pyO ligands.

In compounds $\mathrm{Ph} E(\mathrm{pyO})_{3} E=\mathrm{Si}$, Ge the tetrel atom is essentially tetracoordinate, whereas in $\mathrm{PhSn}(\mathrm{pyO})_{3}$ the tin atom is clearly heptacoordinate within a pentagonal bipyramidal coordination sphere. In the latter, O1 and C16 occupy the axial positions (O1-Sn1-C16 $\left.161.61(14)^{\circ}\right)$, and the equatorial angles of pairs of neighboring bonds are $58.1(1)^{\circ}(\mathrm{O} 3-\mathrm{Sn} 1-$ N3) and $59.2(1)^{\circ}(\mathrm{O} 2-\mathrm{Sn} 1-\mathrm{N} 2)$ for the two chelate motifs and ca. $80^{\circ}$ in the case of the remaining three angles spanned by O2,N1 $\left(80.4(1)^{\circ}\right)$; O3,N2 $\left(79.7(1)^{\circ}\right)$; N1,N3 (80.4(1) ${ }^{\circ}$ ). Nonetheless, the molecular metrics of $\mathrm{PhGe}(\mathrm{pyO})_{3}$ already hint at a transition toward hypercoordination of the heavy tetrel atom. Whereas the $E-\mathrm{O}$ bond lengths increase in an expected manner with an increasing atomic radius of $E$, the $E \cdots \mathrm{~N}$ separations already undergo some significant shortening (by more than $0.1 \AA$ on average) upon going from $E=S i$ to Ge. Thus, with respect to the N atom's van der Waals radius of $1.55 \AA$ and the tetrels' van der Waals radii of $2.10(\mathrm{Si}), 2.11(\mathrm{Ge})$, and $2.17 \AA(\mathrm{Sn})$ [25], the average $E \cdots \mathrm{~N}$ separations are $81.9 \%, 78.5 \%$, and $61.8 \%$ of the sum of van der Waals radii for the $\mathrm{Si}, \mathrm{Ge}$, and Sn compound, respectively. Further evidence for pronounced $E \cdots \mathrm{~N}$ attraction upon going from $E=S i$ to Ge can be found in the O-C-N angle deformation of all pyridine-2-olate groups. Whereas in the silicon compound the O-C-N angles and their corresponding O-C-C angles are very similar (both ca. $117.5^{\circ}$ ), the O-C-N angles in the Ge compound are slightly smaller than the corresponding O-C-C angles, thus indicating the pronounced attractive $\mathrm{Ge} \cdots \mathrm{N}$ interaction. At the Ge atom in compound $\mathrm{PhGe}(\mathrm{pyO})_{3}$, the trend of bond angles adheres to VSEPR, i.e., within the $\mathrm{GeC}_{1} \mathrm{O}_{3}$ coordination sphere, all $\mathrm{O}-\mathrm{Ge}-\mathrm{O}$ angles are smaller than the tetrahedral angle. In sharp contrast, $\mathrm{PhSi}(\mathrm{pyO})_{3}$ features one very small $\mathrm{O}-\mathrm{Si}-\mathrm{O}$ angle (O1-Si1-O3 96.91(6) ${ }^{\circ}$ ), whereas the other two O-Si-O angles (112.54(6) and $\left.115.85(6)^{\circ}\right)$ are noticeably wider than the tetrahedral angle. (Similar features are found in compound $\mathrm{MeSi}(\mathrm{pyO})_{3}$ [2].) This phenomenon can be attributed to the molecular conformation of $\mathrm{PhSi}(\mathrm{pyO})_{3}$ with respect to its enhanced coordination sphere (i.e., [4+3]-coordination). In the case of $\mathrm{PhGe}(\mathrm{pyO})_{3}$, each of the pyridine N atoms is capping a tetrahedral face trans to a Ge-O bond and thus widens the O-Ge-C angles. The tetrahedral face trans to the Ge-C bond lacks this effect and thus allows for mutual shrinkage of the O-Ge-O angles (sum of $\mathrm{O}-\mathrm{Ge}-\mathrm{O}$ angles $302.7^{\circ}$ ). In the case of $\mathrm{PhSi}(\mathrm{pyO})_{3}, \mathrm{~N} 2$ is capping the tetrahedral face trans to the $\mathrm{Si}-\mathrm{C}$ bond and thus widens the $\mathrm{O}-\mathrm{Si}-\mathrm{O}$ angles (sum of $\mathrm{O}-\mathrm{Si-O}$ angles $325.3^{\circ}$ ). As the tetrahedral face trans to $\mathrm{Si} 1-\mathrm{O} 2$ is devoid of a remote donor atom (thus not exerting any additional widening to angle O1-Si1-O3), and the capping of tetrahedral faces by N1 and N3 enforces further widening of angles O1-Si1-O2 and O3-Si1-O2, respectively, bond angle O1-Si1-O3 becomes particularly narrow. Noteworthy, with respect to the overall deformation of the tetrahedral coordination sphere about the tetrel atom, the geometry parameter $\tau_{4^{\prime}}$ [26] (Si: $0.91, \mathrm{Ge}: 0.83$ ) indicates particular deformation in the case of the Ge compound. It originates from a noticeably wide angle O2-Ge1-C16 (124.3(1) ${ }^{\circ}$ ). This feature arises from a $\mathrm{C}-\mathrm{H} \cdots \mathrm{N} 2$ contact, in which a phenyl ortho-H atom interferes with pyridine atom N2 and thus competes with the capping of the tetrahedral face trans to Ge1-O1 by atom N2.

In addition to visualizing the conformational differences between the two [4+3]coordinate tetrel compounds $\mathrm{PhSi}(\mathrm{pyO})_{3}$ and $\mathrm{PhGe}(\mathrm{pyO})_{3}$, the view in Figure 2 demonstrates the relationship of the conformation of $\mathrm{PhGe}(\mathrm{pyO})_{3}$ and the conformation of the pentagonal bipyramidal Sn -coordination compound $\mathrm{PhSn}(\mathrm{pyO})_{3}$. Scheme 2 illustrates this hypothetical transition, starting from the molecular conformation of $\mathrm{PhGe}(\mathrm{pyO})_{3}$ (Scheme 2 a ). In addition to the N atoms approaching the tetrel $E$, partial rotation of the pyO ligands indexed with " 2 " and " 3 " about the bonds shown with rotation arrows in Scheme 2a,b affords the molecular configuration of $\mathrm{PhSn}(\mathrm{pyO})_{3}$ (Scheme 2c).

(a)

(b)

(c)

Scheme 2. Schematic representation of the ligand motion (of corresponding pyO moieties " $\mathbf{1}$ ", " 2 " and " 3 ") which relates the molecular conformations of $\mathrm{PhGe}(\mathrm{pyO})_{3}$ (starting point (a)) and $\mathrm{PhSn}(\mathrm{pyO})_{3}$ (represented by (c)) to one another via (b).

The increasing intensity of $\mathrm{N} \cdots E$ coordination in the series $E=\mathrm{Si}<\mathrm{Ge}<\mathrm{Sn}$ is also reflected by the systematic changes in corresponding bond lengths within the pyO moieties (Table A2). Whereas most bond length differences merely allow for a vague hint at a trend (the changes, albeit seemingly systematic, are not significant within the boundaries of the standard deviations), significant shortening of the $\mathrm{C}-\mathrm{O}$ bonds and, to a lesser extent, lengthening of the adjacent $\mathrm{C}-\mathrm{N}$ bond is observed. Thus, the response of the pyO ligand 's $\mathrm{C}-\mathrm{C}-$ bond backbone to mono- vs. bidentate coordination is less pronounced than the response of the related N -oxide (1-oxy-2-pyridinone, OPO ) in compound $(t \mathrm{Bu})_{2} \mathrm{Si}(\mathrm{OPO})_{2}$, which features both a monodentate and a chelating OPO moiety within the same molecule [27].

The molecular conformation of $\mathrm{PhSn}(\mathrm{pyO})_{3}$ requires some further discussion in context with the literature data. Even though this is the first crystallographically characterized "simple" stannane with more than one pyO substituent, some related compounds of the type $R S n(p y S)_{3}$ (pyS = pyridine-2-thiolate) have been reported and characterized crystallographically (with $\mathrm{R}=\mathrm{p}$-tolyl [28], Me and Ph [29]). In these compounds, the Sn atom is also heptacoordinate within an almost pentagonal bipyramidal coordination sphere, and the hydrocarbyl group as well as one chelate ligand's chalcogen atom occupy axial positions. Their equatorial chelate ligands, however, are arranged in a cis fashion (thus giving rise to an equatorial $\mathrm{N}, \mathrm{N}, \mathrm{N}, \mathrm{S}, \mathrm{S}$ atom sequence), whereas in $\mathrm{PhSn}(\mathrm{pyO})_{3}$ trans-arrangement of the two equatorial chelates is found (and an equatorial $\mathrm{N}, \mathrm{N}, \mathrm{O}, \mathrm{N}, \mathrm{O}$ atom sequence arises therefrom). With a different ( $\mathrm{O}, \mathrm{N}$ )-bidentate ligand system (ox = oxinate, 8-quinolinolate), compound $\mathrm{RSn}(\mathrm{ox})_{3}$ ( $\mathrm{R}=4$-chlorophenyl) with pentagonal bipyramidal Sn coordination sphere has been reported [30]. The conformation of this compound is less related to $\mathrm{PhSn}(\mathrm{pyO})_{3}$ as it exhibits two differences: mutual cis-arrangement of the equatorial chelates and N -axial-O-equatorial arrangement of the third chelate ligand. Figure 3 illustrates this conformational difference.

$\mathrm{R}=\mathrm{Ph}$,
$\mathrm{R}=\mathrm{p}$-Tol, $\mathrm{Ph}, \mathrm{Me}$,
$\mathrm{R}=\mathrm{p}-\mathrm{Cl}-\mathrm{C}_{6} \mathrm{H}_{4}$,
$(\mathrm{ON})=$ pyridine-2-olate
(SN) = pyridine-2-thiolate
$(\mathrm{ON})=8$-quinolinolate
Figure 3. Generic illustration of the conformational difference between $\mathrm{PhSn}(\mathrm{pyO})_{3}$, related pyridine-2-thiolates $\mathrm{RSn}(\mathrm{pyS})_{3}[28,29]$ and 8-quinolinolate $\left(4-\mathrm{Cl}_{6}-\mathrm{C}_{6}\right) \mathrm{Sn}(\mathrm{ox})_{3}[30]$. The motifs " $\mathrm{N}-\mathrm{O}$ " and " $\mathrm{N}-\mathrm{S}^{\prime}$ " serve as abbreviations of the different bidentate $(\mathrm{N}, \mathrm{O})$ - and ( $\mathrm{N}, \mathrm{S}$ )-donor ligands.

Apart from the comparison of $\mathrm{PhSn}(\mathrm{pyO})_{3}$ with more or less related organotintris(chelates) with pentagonal bipyramidal Sn coordination sphere, the context of $(\mathrm{Si}, \mathrm{Ge}, \mathrm{Sn})$ hypercoordination within related four-membered ( $\mathrm{E}, \mathrm{O}, \mathrm{C}, \mathrm{N}$ )-chelate rings formed by monoanionic chelators and tetravalent tetrels must be addressed. A search in the Cambridge

Crystal Structure Database [7] yielded a very limited number of ( $\mathrm{Si}, \mathrm{Ge}, \mathrm{Sn}$ )-compounds with hypercoordinate (i.e., coordination number greater than four) tetrel atoms and such monoanionic ( $\mathrm{O}, \mathrm{N}$ )-chelating ligands. In the case of silicon, the portfolio is limited to three different compounds with hexacoordinate Si atoms, VII [31], VIII [32], and IX [33] (Figure 4). Enhanced Lewis acidity of the Si atom (caused by one or combinations of the parameter(s) such as small rings, electron-withdrawing substituents, and the cationic nature of the complex) may be an essential prerequisite. No representatives of hypercoordinate Ge compounds were found. Even the portfolio of structurally characterized hypercoordinate tetravalent tin compounds with this structural motif is very limited. For tin coordination numbers 6, 7, and 8, no appropriate hits were encountered. For Sn coordination number 7 only one multinuclear tin complex was found which features an ( $\mathrm{Sn}, \mathrm{O}, \mathrm{C}, \mathrm{N}$ )-chelate within a greater system of charge-delocalized multidentate ligands [34]. Even with tin coordination number 5, only two representatives (compounds $\mathbf{X}$ ) were encountered. Interestingly, their four-membered (Sn,O,C,N)-chelates are derived from the pyridine-2-olate system [35].

Figure 4. Literature known examples of structurally confirmed hypercoordinate tetravalent tetrel (E) compounds (compounds VII-X) with (E,O,C,N)-four-membered rings formed by mono-anionic ( $\mathrm{O}, \mathrm{N}$ )-chelating ligands.

In summary, structural characterization of hypercoordinate tetrels with four-membered ( $E, \mathrm{O}, \mathrm{C}, \mathrm{N}$ )-chelates by mono-anionic chelators is still a rather unexplored field. With respect to pyridine-2-olate as a simple representative of such ligands, we may conclude that in the case of silicon compounds the lower tendency of the light tetrel toward hypercoordination can be seen as the major reason, as shown with $\mathrm{PhSi}(\mathrm{pyO})_{3}$ and other examples [1-3]. In the case of Sn compounds, however, the lack of crystallographic evidence for solely $\mathrm{Sn}-\mathrm{O}$ bound pyridine-2-olates with non-coordinating pyridine N atom [7] and the previously mentioned lack of structurally characterized Sn -pyO-chelates is highlighting a field of tetrel coordination chemistry yet to be explored.

### 3.2. NMR Spectroscopic Analyses of $\mathrm{PhE}(\mathrm{pyO})_{3}(E=S i, G e, S n)$

Compounds $\mathrm{Ph} E(\mathrm{pyO})_{3}(E=\mathrm{Si}, \mathrm{Ge}, \mathrm{Sn})$ were characterized by NMR spectroscopy in $\mathrm{CDCl}_{3}$ solution and, in the case of $\mathrm{PhSn}(\mathrm{pyO})_{3}$, with ${ }^{119} \mathrm{Sn}$ solid-state NMR spectroscopy.

In the $\mathrm{CDCl}_{3}$ solution, the Si atom of compound $\mathrm{PhSi}(\mathrm{pyO})_{3}$ is tetracoordinate, indicated by $\delta{ }^{29} \mathrm{Si}=-64.7 \mathrm{ppm}$. This signal is upfield shifted with respect to that of the corresponding methyl compound $\mathrm{MeSi}(\mathrm{pyO})_{3}\left(\delta^{29} \mathrm{Si}=-46.5 \mathrm{ppm}\right.$ [2]), which is a common observation with pairs of corresponding PhSi and MeSi compounds (e.g., $\mathrm{PhSi}(\mathrm{OEt})_{3} \delta^{29} \mathrm{Si}=-57.8 \mathrm{ppm}$ [36], $\mathrm{MeSi}(\mathrm{OEt})_{3} \delta^{29} \mathrm{Si}=-44.5 \mathrm{ppm}$ [37]). In principle, compound $\mathrm{PhSi}(\mathrm{pyO})_{3}$ has a similar ${ }^{29} \mathrm{Si}$ NMR shift as the tetracoordinate phenyl silicon compound $\mathrm{PhSi}(\mathrm{OEt})_{3}$.

For compound $\mathrm{PhSn}(\mathrm{pyO})_{3}$ the ${ }^{119} \mathrm{Sn}$ NMR shifts were recorded in the solid state $\left(-617 \mathrm{ppm}\right.$, Figure 5) as well as in $\mathrm{CDCl}_{3}$ at different temperatures $\left(20^{\circ} \mathrm{C}:-609 \mathrm{ppm}\right.$, $-40^{\circ} \mathrm{C}$ : $\left.-614 \mathrm{ppm}\right)$. These chemical shifts are basically speaking for retention of the tin coordination number 7 in the $\mathrm{CDCl}_{3}$ solution. Furthermore, these shifts are similar to those
of other stannanes with heptacoordinate Sn atom and $\operatorname{ArylSn}(\mathrm{O}, \mathrm{N})_{3}$ coordination, e.g., p-TolSn(quinoline-8-olate) $3_{3}(-611 \mathrm{ppm}), \mathrm{p}-\mathrm{TolSn}(\text { pyridine-2-carboxylate })_{3}(-620 \mathrm{ppm})$ [30].

Figure 5. ${ }^{29}$ Si MAS NMR spectrum of $\mathrm{PhSn}(\mathrm{pyO})_{3}$ recorded at a spinning frequency of 13 kHz (top, red trace) and simulated spectrum using the CSA tensor data derived from the experimental spectrum (bottom, blue trace). The asterisked ( ${ }^{*}$ ) peaks are spinning sidebands. CSA tensor data: $\delta_{\text {iso }}-617.4 \mathrm{ppm}, \delta_{11}-393.5 \mathrm{ppm}, \delta_{22}-502.2 \mathrm{ppm}, \delta_{33}-956.5 \mathrm{ppm}, \Omega 563 \mathrm{ppm}, \kappa 0.61$.

In the ${ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}$ NMR spectra of each of the compounds $\mathrm{Ph} E(\mathrm{pyO})_{3}(E=\mathrm{Si}, \mathrm{Ge}, \mathrm{Sn})$, the three pyO moieties give rise to one set of four $\left({ }^{1} \mathrm{H}\right)$ or five $\left({ }^{13} \mathrm{C}\right)$ signals, which was expected at least for the Si compound in accord with previously reported pyO-functionalized silanes $[2,3]$. In the case of compound $\mathrm{PhSn}(\mathrm{pyO})_{3}$, it confirms that the $\mathrm{SnCN}_{3} \mathrm{O}_{3}$ coordination sphere itself is highly flexible and undergoes rapid exchange processes. Even cooling to $-40^{\circ} \mathrm{C}$ did not cause any signal broadening or decoalescence effects (Figure 6).

Figure 6. Section of the ${ }^{1} \mathrm{H}$ NMR spectra of $\mathrm{CDCl}_{3}$ solutions of (from bottom to top) $\mathrm{PhSi}(\mathrm{pyO})_{3}$, $\mathrm{PhGe}(\mathrm{pyO})_{3}$, and $\mathrm{PhSn}(\mathrm{pyO})_{3}$ at room temperature as well as of $\mathrm{PhSn}(\mathrm{pyO})_{3}$ at $-40{ }^{\circ} \mathrm{C}$. The spectra are internally referenced to $\mathrm{SiMe}_{4}$ (cf. spectra shown in Figures S1, S4, and S6 in the supplementary material).

To evaluate the pyO@Ge coordination chemistry of $\mathrm{PhGe}(\mathrm{pyO})_{3}$ in $\mathrm{CDCl}_{3}$ solution, a comparison of ${ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}$ NMR spectra of this compound with those of the lighter and heavier congener was engaged. In ${ }^{13} \mathrm{C}$ NMR spectra, it was found that the $C^{2}$ and $\mathrm{C}^{6}$ positions of the pyO groups are highly responsive to coordinative changes at the N atom. In the spectrum of a $\mathrm{CDCl}_{3}$ solution of compound $\mathrm{PhP}(\mathrm{pyO})_{2}$ [13] the signals of interest emerge at $161.8 \mathrm{ppm}\left(\mathrm{C}^{2}\right)$ and $147.4 \mathrm{ppm}\left(\mathrm{C}^{6}\right)$. The spectrum of the related compound $\mathrm{PhSb}(\mathrm{pyO})_{2}$ [38], which exhibits pronounced $\mathrm{Sb} \cdots \mathrm{N}$ attraction, exhibits the
corresponding signals at $167.0 \mathrm{ppm}\left(\mathrm{C}^{2}\right)$ and $140.6 \mathrm{ppm}\left(\mathrm{C}^{6}\right)$. The corresponding signals of the related arsenic compound $\mathrm{PhAs}(\mathrm{pyO})_{2}$ [39] emerge at intermediate positions. Even though this trend may also be influenced by electronic effects through the $\mathrm{E}-\mathrm{O}-\mathrm{C}_{5} \mathrm{~N}$ $\sigma$ - and $\pi$-bond system (originating from different $E-O$ bonds caused by the different elements $E$ ), the relevance of the electronic effects caused by $\mathrm{N} \rightarrow$ tetrel coordination is underlined by corresponding data of a set of literature known pyridine-2-thiolate (pyS) compounds $[3,40,41]$, which show that the same trends are observed for $C^{2}$ and $C^{6}$, but these trends are more responsive to hypercoordination $(E(S, N)$-chelation vs. absence of $E \cdots \mathrm{~N}$ coordination) rather than to the element $E$ itself (cf. Table A3).

The ${ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}$ NMR spectra of compound $\mathrm{PhGe}(\mathrm{pyO})_{3}$ in $\mathrm{CDCl}_{3}$ solution resemble both the signal patterns ( ${ }^{1} \mathrm{H}$ coupling patterns) and the chemical shifts of corresponding signals (both ${ }^{1} \mathrm{H}$ and ${ }^{13} \mathrm{C}$ ) of the related silicon compound. For a comparison of their ${ }^{1} \mathrm{H}$ NMR signals, see Figure 6. For the series of spectra of $\operatorname{Ph} E(p y O)_{3}(E=\mathrm{Si}, \mathrm{Ge}, \mathrm{Sn})$ recorded at room temperature, systematic shift trends are observed for corresponding ${ }^{1} \mathrm{H}$ signals of the pyO moieties. The upfield shift of the ${ }^{1} \mathrm{H}$ NMR signal of the pyO protons in position 6 from $E=\mathrm{Si}$ via Ge to Sn is the most prominent trend among their $\mathrm{pyO}^{1} \mathrm{H}$ signals and thus underlines the changes in $\mathrm{N} \cdots E$ coordination, which can be derived from ${ }^{13} \mathrm{C}$ NMR data (Table 2). A trend toward hypercoordination of the Ge atom is indicated by the ${ }^{13} \mathrm{C}$ NMR shifts of the pyO carbon atoms in positions 2 and 6 . Their signals are further downfield shifted ( $\mathrm{C}^{2}$, by 3 ppm ) and upfield shifted $\left(\mathrm{C}^{6}\right.$, by 1.4 ppm$)$ in the Ge compound.

Table 2. ${ }^{13} \mathrm{C}$ NMR shifts of $\mathrm{C}^{2}$ and $\mathrm{C}^{6}$ of the pyridine-2-olate ( pyO ) ligands of compounds $\mathrm{Ph} E(\mathrm{pyO})_{3}$ in $\mathrm{CDCl}_{3}$.

| Compound | $E \cdots \mathrm{~N}(\mathrm{pyS})$ Coordination? ${ }^{1}$ | $\delta^{13} \mathrm{C}\left(\mathrm{C}^{2}\right)$ | $\delta^{13} \mathrm{C}\left(\mathrm{C}^{6}\right)$ |
| :---: | :---: | :---: | :---: |
| $\mathrm{PhSi}(\mathrm{pyO})_{3}$ | 0 | 160.3 | 147.3 |
| $\mathrm{PhGe}(\mathrm{pyO})_{3}$ | intermediate | 163.3 | 145.9 |
| $\mathrm{PhSn}(\mathrm{pyO})_{3}$ | 1 | 167.0 | 141.8 |

${ }^{1}$ According to the number of pyO groups in the molecule and the coordination number of $E$, all pyO groups (1) or no pyO groups (0) establish $E \cdots \mathrm{~N}$ coordination. The ${ }^{13} \mathrm{C}$ NMR shift trends indicate intermediate $E \cdots \mathrm{~N}$ coordination for the Ge compound.

## 4. Conclusions

In general, compounds such as the herein presented set $\mathrm{Ph} E(\mathrm{pyO})_{3}$ represent potential starting materials for the syntheses of heteronuclear complexes. For compounds such as $\mathrm{MeSi}(\mathrm{pyO})_{3}$ [2], $\mathrm{Si}(7 \text {-azaindolyl })_{4}$ [42], $\mathrm{ClSi}(\mathrm{mt})_{3}$ [43], $\mathrm{Si}(\mathrm{mt})_{4}$ [44], $\mathrm{FPhE}\left(\mathrm{o}-\mathrm{C}_{6} \mathrm{H}_{4}-\right.$ $\left.\mathrm{PiPr}_{2}\right)_{2}(E=\mathrm{Si}, \mathrm{Sn})$ [45], $\mathrm{FE}\left(\mathrm{o}-\mathrm{C}_{6} \mathrm{H}_{4}-\mathrm{PPh}_{2}\right)_{3}(E=\mathrm{Si}, \mathrm{Ge}, \mathrm{Sn})$ [46], $\mathrm{FSi}\left(\mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{PMe}_{2}\right)_{2}$ [47], $\mathrm{MeSi}\left(\mathrm{OCH}_{2} \mathrm{PMe}_{2}\right)_{2}\left(\mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{PMe}_{2}\right)$ [48] it has been shown that their dangling donor atoms ( $\mathrm{N}, \mathrm{S}, \mathrm{P}$ ) may bind to transition metals and, in some cases, foster establishing of formally dative bonding of the transition metal to the tetrel. As dangling donor arms of their potentially bidentate substituents may be essential for binding to another metal atom (because of the absence of other reactive groups within the molecule), compounds $\mathrm{PhSi}(\mathrm{pyO})_{3}$ and $\mathrm{PhGe}(\mathrm{pyO})_{3}$ with their absent or poor $E \cdots \mathrm{~N}$ coordination appear more suitable for that purpose than the related tin compound, in which the N atoms are engaged in a competing situation, i.e., $\mathrm{Sn} \cdots \mathrm{N}$ coordination also in solution. The flexibility/mobility of the Sn coordination sphere, however, may still render compounds such as $\mathrm{PhSn}(\mathrm{pyO})_{3}$ suitable for the same purpose. Detailed studies of the ligand qualities of Ge- and Sn -pyO-compounds are yet to be performed. For compounds of the type $\operatorname{RSi}(p y O)_{3}$ we had already confirmed the suitability as a ligand for $\mathrm{Cu}(\mathrm{I})$ in the case of $\mathrm{R}=\mathrm{Me}$ [2], and a study of related silanes ( $\mathrm{R}=\mathrm{Ph}$, Benzyl, Allyl) is currently underway.

Supplementary Materials: The following supporting information can be downloaded at: https:// www.mdpi.com/article/10.3390/cryst12121802/s1: NMR spectra $\left({ }^{1} \mathrm{H},{ }^{13} \mathrm{C}\left\{{ }^{1} \mathrm{H}\right\}\right.$ and, where applicable, ${ }^{29} \mathrm{Si}\left\{{ }^{1} \mathrm{H}\right\}$ or ${ }^{119} \mathrm{Sn}\left\{{ }^{1} \mathrm{H}\right\}$ ) of $\mathrm{CDCl}_{3}$ solutions of compounds $\mathrm{PhSi}(\mathrm{pyO})_{3}$ (Figures $\left.\mathrm{S} 1-\mathrm{S} 3\right)$, $\mathrm{PhGe}(\mathrm{pyO})_{3}$ (Figures S4, S5), and $\mathrm{PhSn}(\mathrm{pyO})_{3}$ (Figures S6-S9).

Author Contributions: Conceptualization, J.W.; investigation, S.K., E.B., and J.W.; writing-original draft preparation, J.W.; writing-review and editing, E.B. and J.W.; visualization, J.W.; supervision, J.W. All authors have read and agreed to the published version of the manuscript.

Funding: This research received no external funding.
Institutional Review Board Statement: Not applicable.
Informed Consent Statement: Not applicable.
Data Availability Statement: Not applicable.
Acknowledgments: The authors are grateful to Beate Kutzner, Franziska Gründler, and Mareike Weigel (TU Bergakademie Freiberg, Institut für Anorganische Chemie) for solution NMR (B.K.) and elemental microanalysis service (F.G., M.W.), and to the students Alexandra Becker and Arthur Hentschel (TU Bergakademie Freiberg) for preparing additional batches of compound $\mathrm{PhSi}(\mathrm{pyO})_{3} \cdot$ THF.
Conflicts of Interest: The authors declare no conflict of interest.

## Appendix A

${ }^{1}$ For clarity of presentation, groups of corresponding bonds within the set of individual ligands of each molecule were summarized within a block of the same shading.

Table A3. ${ }^{13} \mathrm{C}$ NMR shifts of $\mathrm{C}^{2}$ and $\mathrm{C}^{6}$ of the pyridine-2-thiolate (pyS) ligands of a series of related silicon and tin compounds in $\mathrm{CDCl}_{3}$ or $\mathrm{CD}_{2} \mathrm{Cl}_{2}$ solution.

| Compound | E | Solvent | $E \cdots \mathrm{~N}(\mathrm{pyS})$ Coordination ${ }^{1}{ }^{1}$ | $\delta^{13} \mathrm{C}(\mathrm{C} 2)$ | $\delta^{13} \mathrm{C}(\mathrm{C} 6)$ |
| :---: | :---: | :---: | :---: | :---: | :---: |
| $\mathrm{PhClSi}(\mathrm{pyS})_{2}$ [40] | Si | $\mathrm{CD}_{2} \mathrm{Cl}_{2}$ | 1 | 167.5 | 140.8 |
| $\mathrm{MeClSi}(\mathrm{pyS})_{2}$ [40] | Si | $\mathrm{CD}_{2} \mathrm{Cl}_{2}$ | 1 | 168.1 | 140.4 |
| $\mathrm{Si}(\mathrm{pyS})_{4}[41]$ | Si | $\mathrm{CDCl}_{3}$ | 0.5 | 163.4 | 144.7 |
| $\mathrm{Sn}(\mathrm{pyS})_{4}[41]$ | Sn | $\mathrm{CDCl}_{3}$ | 0.5 | 162.9 | 145.7 |
| $\mathrm{Ph}_{2} \mathrm{Si}(\mathrm{pyS})_{2}$ [3] | Si | $\mathrm{CDCl}_{3}$ | 0 | 158.1 | 147.5 |
| $\mathrm{Me}_{2} \mathrm{Si}(\mathrm{pyS})_{2}$ [3] | Si | $\mathrm{CDCl}_{3}$ | 0 | 158.7 | 148.8 |

${ }^{1}$ According to the number of pyS groups in the molecule and the coordination number of $E$, all pyS groups (1) or no pyS groups ( 0 ) establish $E \cdots \mathrm{~N}$ coordination. In the case of compounds $E(\mathrm{pyS})_{4}$, the coordination number of $E$ is 6 . In these compounds, two $E \cdots \mathrm{~N}$ coordinating and two non- $E \cdots \mathrm{~N}$-coordinating pyS groups exchange in a dynamic equilibrium (thus, a formal contribution of 0.5 of each pyS group to the overall $E \cdots \mathrm{~N}$ coordination arises therefrom).

#### Abstract

The synthesis, crystal structures, and luminescence of two lanthanide polynuclear complexes with the general formula $\left[\mathrm{Ln}_{2}\left(\mathrm{tda}_{3}\left(\mathrm{H}_{2} \mathrm{O}\right)_{5}\right] \cdot 3 \mathrm{H}_{2} \mathrm{O}(\mathrm{Ln}=\mathrm{Sm}\right.$, Eu; tda = thiodiacetato anion) are reported. The compounds were obtained by direct reaction of $\mathrm{H}_{2}$ tda and lanthanide(III) chloride in an aqueous solution. The choice of the conditions of synthesis was based on speciation studies. The structure of the polymeric complexes contains $\operatorname{Ln}$ (III) ions in a tricapped trigonal prism geometry. The versatility of this ligand provides different coordination modes and provokes the formation of thick 2D sheets. Direct excitation of the $\operatorname{Ln}$ (III) ions gives place to the characteristic intra-configuration sharp luminescence emission of both complexes in the solid state.

Keywords: lanthanide complexes; crystal structure; chemical speciation; thiodiacetato complex

## 1. Introduction

The study of lanthanide(III) (Ln) coordination compounds has elicited considerable interest in the last decades [1-4]. Different coordination numbers and geometries can give place to novel and interesting crystal structures. In addition, they have great potential as functional solid materials such as luminescent materials [5], magnetic devices [6], chemical sensors $[7,8]$, etc. We and other groups have been interested in Ln (III) mononuclear and polynuclear complexes with ligands of type $\mathrm{X}-\left(\mathrm{CH}_{2}-\mathrm{COO}\right)_{2}{ }^{2-}$, where $\mathrm{X}=\mathrm{O}$ (oxydiacetato, oda $^{2-}$ ), NH (iminodiacetato, ida ${ }^{2-}$ ) or S (thiodiacetato, tda ${ }^{2-}$ ) [9]. Oxydiacetato, the most deeply studied ligand of this group, appears as the most suitable ligand for Ln ions because of the presence of three O donor atoms in its structure. Hence, many complexes were already reported and characterized [9-13]. The thermodynamic stability of Ln-oda complexes also allows the use of the tris-chelate $\left(\left[\operatorname{Ln}(\operatorname{oda})_{3}\right]^{3-}\right)$ as a complex-as-ligand block towards M (II) cations [9,14]. The resulting heteropolynuclear compounds were assayed as catalysts [15,16], white-light emitters [17], and proton conductive MOF-based materials [18]. Iminodiacetato, with an N atom in the center, has also been studied, but to a lesser extent [9]. Substitution of O in oda by N in ida provokes a poorer participation of N in the coordination $[14,19]$, which has hindered the isolation of tris-chelates.

Thiodiacetato is the less explored member of this series of ligands. The combination of O-carboxylate (hard donor atom) with sulfur (soft donor atom) makes the chemistry of this ligand very versatile and, at the same time, very challenging. Several structural reports show its capacity to act as a tridentate ligand towards Cu (II) [20-23], Ni (II) [24-29] Co (II) [30-36], Mn (II) [37], Zn (II) [38-40], Cd (II) [41], Mg (II) [42], $\operatorname{Re}(\mathrm{V})$ [43], V(IV) [44], and $\mathrm{Ru}($ III ) [45]. However, only one report can be found containing a bis-chelated fragment in a mononuclear compound [32], namely, $\left(\mathrm{pipH}_{2}\right)\left[\mathrm{Co}(\mathrm{tda})_{2}\right] \cdot 2 \mathrm{H}_{2} \mathrm{O}\left(\mathrm{pipH}_{2}{ }^{2+}=\right.$ piperazine dication). The other structures always contain a coligand. The possibility of acting as
a bidentate ligand ( $\mathrm{O}, \mathrm{O}$ or $\mathrm{O}, \mathrm{S}$ ) for these metal ions is restricted to a few cases [46,47]. Thiodiacetato ligand also exhibits the possibility of forming a bridge between metal ions, yielding polynuclear complexes. This can be found in structures with $\mathrm{Cu}(\mathrm{II})$ [20,48-50], $\mathrm{Mn}(\mathrm{II})$ [37,49,51], and $\mathrm{Zn}(\mathrm{II})$ [52-54].

Coordination compounds of tda with Ln ions are even less frequent. Anionic isolated tris-chelates have been reported in $\left(\mathrm{H}_{2} \mathrm{Gun}\right)_{3}\left[\mathrm{Ln}(\mathrm{tda})_{3}\right](\mathrm{Ln}=\mathrm{Pr}, \mathrm{Nd}, \mathrm{HGun}=$ guanidinium, $\left.\mathrm{C}\left(\mathrm{NH}_{2}\right)_{3}{ }^{+}\right)$[55]. In these structures, tda acts as bidentate through two O-carboxylate atoms, forming an 8 -membered ring. S atom is $3.423 \AA$ apart from Ln ion and does not participate in the coordination sphere. Another report presents a polynuclear compound with the formula $\left[\mathrm{Nd}(\mathrm{tda})\left(\mathrm{H}_{2} \mathrm{O}\right)_{4}\right] \mathrm{Cl}[56]$. In this compound, tda acts as tridentate and additionally bridges Nd ions through carboxylate groups. A zigzag chain is formed. $\mathrm{Nd}(\mathrm{III})$ also forms an anionic 2D network in the complex $\mathrm{Na}\left[\mathrm{Nd}(\mathrm{tda})_{2}\right]$, in which the S atom is not coordinated, and the coordination sphere is filled only by O atoms from tda [57]. The structure of $\left(\mathrm{pipH}_{2}\right)\left[\mathrm{Ce}_{2}(\mathrm{tda})_{4}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}\right] \cdot 3 \mathrm{H}_{2} \mathrm{O}$ is also a 2D anionic structure [58]. Finally, other groups of 2D polynuclear structures can be found. In $\left[\mathrm{Ln}_{2}(\mathrm{tda})_{3}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}\right]_{\mathrm{n}}(\mathrm{Ln}=\mathrm{La}$, $\mathrm{Sm}, \mathrm{Gd}, \mathrm{Nd}, \mathrm{Pr}, \mathrm{Tb}, \mathrm{Dy}, \mathrm{Eu})$, tda acts as bidentate and also as a ditopic ligand. The S atom seems to participate in the coordination but at a rather long distance [59-63].

In order to increase the knowledge of tda as a ligand towards Ln ions, we have revisited the solution chemistry of the systems by potentiometry and prepared, under mild reaction conditions, complexes with the general formula $\left[\mathrm{Ln}_{2}(\mathrm{tda})_{3}\left(\mathrm{H}_{2} \mathrm{O}\right)_{5}\right] \cdot 3 \mathrm{H}_{2} \mathrm{O}$ $(\mathrm{Ln}=\mathrm{Sm}(1), \mathrm{Eu}(2))$. They show a new 2D structural arrangement. Solid-state luminescent properties were also studied.

## 2. Materials and Methods

All chemicals were reagent grade, purchased from commercial sources, and used without purification. $\mathrm{LnCl}_{3} \cdot 6 \mathrm{H}_{2} \mathrm{O}(\mathrm{Ln}=\mathrm{Sm}, \mathrm{Eu}, 99.9 \%$ from Sigma-Aldrich, Burlington, MA, USA) were used as metal sources. Potentiometric measurements were carried out using an automatic titrator Mettler-Toledo DL50-Graphix. Elemental analyses (C, H, and S) were performed on a Thermo FLASH 2000 CHNS/O Analyzer instrument. Infrared spectra were collected as KBr pellets on an FTIR Shimadzu IR-Prestige-21 spectrophotometer from 4000 to $400 \mathrm{~cm}^{-1}$. Thermogravimetric analyses (TGA) were carried out on a Shimadzu TGA-50 instrument with a TA 50 I interface, using a platinum cell and nitrogen atmosphere; the experimental conditions were $0.5^{\circ} \mathrm{C} \mathrm{min}^{-1}$ temperature ramp rate and $50 \mathrm{~mL} \mathrm{~min}^{-1}$ nitrogen flow rate (pure nitrogen was used, water content was less than 3 ppm ). Luminescence spectra were recorded from solid crystalline samples using a SHIMADZU RF-5301Pc spectrofluorometer.

### 2.1. Equilibrium Studies

The standard HCl and NaOH solutions were prepared by diluting Merck standard ampoules. Acid and base stock solutions were standardized against sodium carbonate and potassium hydrogen phthalate, respectively. All solutions were prepared with analyticalgrade water ( $18 \mu \mathrm{~S} \mathrm{~cm}^{-1}$ ) and were freed of carbon dioxide by bubbling with argon. $\mathrm{NaClO}_{4} \cdot \mathrm{H}_{2} \mathrm{O}$ (Sigma-Aldrich $98 \%$ ) was used to adjust the ionic strength of all solutions to $0.15 \mathrm{~mol} \cdot \mathrm{~L}^{-1}$. The temperature was kept at $25.0( \pm 0.1)^{\circ} \mathrm{C}$. The protonation constants of tda ${ }^{2-}$ were determined by two potentiometric titrations (ca. 150 experimental points each) in the interval 1-8 mmol $\cdot \mathrm{L}^{-1}$. The behavior of the ligand in the presence of either Sm (III) or Eu (III) was then analyzed through three potentiometric titrations (ca. 100-150 experimental points each) at ligand to $\mathrm{Ln}(\mathrm{III})$ total molar ratios varying from 1:1 to 3:1. The pH interval from 2.0 to the precipitation of solid $\mathrm{Ln}(\mathrm{OH})_{3}$ in the alkaline region was covered.

In a typical experiment, after thermal equilibrium was reached, hydrogen ion concentrations were determined by successive readings, each performed after an incremental addition of standard $0.1 \mathrm{~mol} \cdot \mathrm{~L}^{-1} \mathrm{NaOH}$ solution. Equilibrium attainment after each titrant addition was verified by controlling the deviation of successive e.m.f. readings. Independent stock solutions were used to check reproducibility. The cell electrode potential $E^{\circ}$
and the acidic junction potential were determined [64] from independent titrations of the strong acid with the titrant solution. The calibration in the alkaline range was checked by recalculating $K_{\mathrm{w}}$ values for each system. The obtained values (average $\log _{10} K_{\mathrm{w}}=13.7$ ) were checked to be in line with previously reported data under the same experimental conditions [65]. The formation constant of soluble hydroxo species of $\operatorname{Ln}$ (III) was taken from a previous report [66] and was included in the input for the calculation of the formation constants. Further details on data analysis can be found elsewhere [67].

### 2.2. X-ray Data Collection and Structure Refinement

X-ray diffraction data on single crystals 1 and 2 were collected with an Agilent SuperNOVA diffractometer with microfocus X-ray using Mo K $\alpha$ radiation ( $\lambda=0.71073 \AA$ ). CrysAlisPro [68] software was used to collect, index, scale and apply a numerical absorption correction based on Gaussian integration over a multifaceted crystal model. The structures were solved using ShelXT [69] program using dual methods and refined by full-matrix least-squares minimization on $F^{2}$ using ShelXL [70] software. All non-hydrogen atoms were refined anisotropically. Hydrogen atom positions were calculated geometrically and refined using the riding model. The geometrical analysis of the interactions in the structures was performed with PLATON [71] and Olex2 [72] programs. Crystal data, collection procedures, and refinement results are summarized in Table 1.

Crystallographic data for the structures reported in this contribution have been deposited with the Cambridge Crystallographic Data Centre as supplementary publication 2224921-224922. Copies of the data can be obtained free of charge on application to the CCDC, Cambridge, U.K. (http:/ /www.ccdc.cam.ac.uk/).

### 2.3. Synthesis of $\left[\operatorname{Ln}_{2}(t d a)_{3}\left(\mathrm{H}_{2} \mathrm{O}\right)_{5}\right] \cdot 3 \mathrm{H}_{2} \mathrm{O}(\mathrm{Ln}=\mathrm{Sm}(1), \mathrm{Eu}$ (2))

$1.35 \mathrm{mmol}(0.203 \mathrm{~g})$ of $\mathrm{H}_{2} \mathrm{tda}$ and 0.45 mmol of $\mathrm{LnCl}_{3} \cdot 6 \mathrm{H}_{2} \mathrm{O}(0.164(1), 0.165(2) \mathrm{g})$ were dissolved in 10 mL of water at room temperature with continuous stirring. Then, the pH of the solution was adjusted to ca. 3.3 with aqueous 0.5 M NaOH . If a small amount of a white solid remained at this point, it was filtered through paper and discarded. The clear solution was allowed to evaporate slowly. After 10 days, a crystalline material was formed, filtrated, washed with two portions of 1 mL of water, and air-dried. Some crystals were suitable for single-crystal X-ray diffraction analysis. Yield: $52 \%$ (1), $61 \%$ (2). ## 3. Results

### 3.1. Solution Studies

For a rational design of the synthetic procedure, the first step of the study was to look at the Ln (III)-tda systems in solution at room temperature and low ionic strength since previously reported data were not conclusive about the species formed, especially in the acid interval in which protonated species were detected by some authors but not by others (Table S1). Protonation equilibrium constants of the ligand (Table 2) were also redetermined under identical conditions: $0.15 \mathrm{~mol} \cdot \mathrm{~L}^{-1} \mathrm{NaClO}_{4}$ at $25.0^{\circ} \mathrm{C}$. The obtained results for the protonation constants are in total agreement with previous reports under similar conditions [65,73,74]. With these results and the previously reported hydrolysis constants of the $\operatorname{Ln}$ (III) ions under similar conditions [66], the stability constants of the species $\operatorname{Ln}(\mathrm{III})$-tda were determined. This is also shown in Table 2. Only cationic species 1:1 $\left([\operatorname{Ln}(\mathrm{tda})]^{+}\right.$and $\left.[\operatorname{Ln}(\mathrm{Htda})]^{2+}\right)$ and the anionic species 1:2 $\left.\left(\mathrm{Ln}(\mathrm{tda})_{2}\right]^{-}\right)$were detected in solution, with similar stability constant values for Sm (III) and Eu (III). It is interesting to compare the stability constants of tda species with those for oda and ida (some of them are also included in Table 2). A close inspection of $\log _{10} K$ values shows that $\mathrm{Ln}(\mathrm{III})$-tda species are much less stable than the analogous complexes with oda or ida. The change of O or N by S as a donor atom represents a loss of stability in the coordination compounds of lanthanide(III) ions.

Table 2. Logarithm of the acid-base and complexation equilibrium constants determined in this work in $0.15 \mathrm{~mol} \cdot \mathrm{~L}^{-1} \mathrm{NaClO}_{4}$ at $25.0^{\circ} \mathrm{C}$. $\mathrm{H}_{2}$ tda represents the fully protonated neutral form of thiodiacetic acid. Values given in parentheses are the $1 \sigma$ statistical uncertainties in the last digit of the determined constant values. Selected stability constants for analogous oda and ida complexes (again, $\mathrm{H}_{2}$ oda and $\mathrm{H}_{2}$ ida represent the fully protonated neutral forms) were taken from selected reported data under similar experimental conditions.

| $\mathrm{Eu}^{3+}+\mathrm{ida}^{2-} \rightarrow[\mathrm{Eu}(\mathrm{ida})]^{+}$ | 6.48 | [77] |
| $\mathrm{Eu}^{3+}+2 \mathrm{ida}^{2-} \rightarrow\left[\mathrm{Eu}(\mathrm{ida})_{2}\right]^{-}$ | 11.65 | [77] |

Figure 1 shows the species distribution diagrams for Sm(III)-tda system built with these results for the ligand-to-metal molar ratios 1:1 and 3:1, while Figure S1 shows similar diagrams for $\mathrm{Eu}(\mathrm{III})$. The low stability of these complexes is reflected in the high percentage of free $\mathrm{Ln}(\mathrm{III})$, especially below $\mathrm{pH} 4-5$. Even though the complex species $[\mathrm{Ln}(\mathrm{Htda})]^{2+}$ is detected in this interval (contrary to what happens in oda or ida-containing systems), the partially protonated ligand gives place to a low-stability species that forms only in a relatively low percentage (the calculated $\log _{10} K$ values for $\mathrm{Ln}^{3+}+\mathrm{Htda}-\rightarrow[\operatorname{Ln}(\mathrm{Htda})]^{2+}$ are 2.0 and 1.5 for Sm and Eu , respectively). It is worth mentioning at this point that the present results are in perfect agreement with previous findings based on the luminescence lifetime measurements of $\mathrm{Eu}(\mathrm{III})$ or Sm (III) ions in the presence of tda in an aqueous solution [78,79]. In particular, these findings suggest the non-participation of the $S$ atom in the coordination sphere, which is in agreement with the formation of much less stable species in comparison to what happens with the analogous oda or ida ligands [78,79]. Besides, similar experiments carried out in the acid interval show the same average number of $c a$. six Sm -coordinated water molecules for conditions in which either $[\mathrm{Sm}(\mathrm{tda})]^{+}$, $[\mathrm{Sm}(\mathrm{Htda})]^{2+}$ or $[\mathrm{Sm}(\mathrm{tda})(\mathrm{Htda})]$ should predominate $[78,80]$. This accounts for the nonexistence of the last species, which was not detected in this work. On the other hand, the hydrolysis of the lanthanide(III) ion at pH values above $7-8$ represents a relevant competitive process to be considered in the synthesis of the compounds. In that sense, just above pH 3 and in the presence of ligand excess, mononuclear species are expected to be present. In contrast, the competition of hydrolysis processes is expected to be minimized.

Figure 1. Species distribution diagram of the Sm -tda system at $25.0^{\circ} \mathrm{C}, I=0.15 \mathrm{~mol} \cdot \mathrm{~L}^{-1} \mathrm{NaClO}_{4}$. Left: total $\left[\mathrm{Sm}^{3+}\right]=1 \mathrm{mM}$ and total $[\mathrm{tda}]=1 \mathrm{mM}$. Right: total $\left[\mathrm{Sm}^{3+}\right]=1 \mathrm{mM}$ and total $[\mathrm{tda}]=3 \mathrm{mM}$.

### 3.2. Synthesis and Characterization

Following our previous strategy to isolate Ln complexes with ida and derivatives [19,81] and taking into account the results of the preceding section, we prepared the complexes $\left[\mathrm{Ln}_{2}(\mathrm{tda})_{3}\left(\mathrm{H}_{2} \mathrm{O}\right)_{5}\right] \cdot 3 \mathrm{H}_{2} \mathrm{O}(\mathrm{Ln}=\mathrm{Sm}(1), \mathrm{Eu}(2))$. An aqueous solution of $\mathrm{LnCl}_{3}$ and $\mathrm{H}_{2}$ tda (molar ratio 1:3, pH 3.3 ) was allowed to evaporate slowly to obtain the crystalline compounds. Preliminary characterization of the solids by elemental analysis is in good agreement with the proposed formula. The IR spectra (Figure S2) were almost identical for both complexes suggesting very similar structures. It is noticeable the shift and splitting of the sharp signals $v_{\mathrm{s}}(\mathrm{COO})\left(1698 \mathrm{~cm}^{-1}\right)$ and $v_{\mathrm{as}}(\mathrm{COO})\left(1430 \mathrm{~cm}^{-1}\right)$ of the free ligand: $\mathbf{1}$ and $\mathbf{2}$ exhibit very strong $v_{\mathrm{s}}(\mathrm{COO})$ signals at 1595 and $1564 \mathrm{~cm}^{-1}$ and $v_{\mathrm{as}}(\mathrm{COO})$ at 1425 and $1383 \mathrm{~cm}^{-1}$. The stoichiometric ratio found in the solids (molar ratio Ln:tda 2:3) is the same as found in the complexes $\left[\mathrm{Ln}_{2}(\mathrm{tda})_{3}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}\right]$ previously reported [57-59]. In those previous reports, the synthesis was performed by solvothermal procedures and, in general, in water: ethanol mixtures.

TGA of the solids (Figure S3) shows a broad weight loss up to $200^{\circ} \mathrm{C}$, corresponding to all the water molecules (calculated for 1, 16.2\%, found $15.2 \%$; calculated for $\mathbf{2}, 16.2 \%$, found $15.3 \%$ ). Decomposition appears in both complexes at ca. $320^{\circ} \mathrm{C}$.

### 3.3. Crystal Structures

It was possible to obtain single crystals of $\mathbf{1}$ and 2 , which crystallize in the triclinic space group $P \overline{1}$. They are isostructural, so we will only discuss the structure of $\mathbf{1}$. Selected bond lengths are presented in Table 3. Two crystallographically non-equivalent Sm atoms are present, both with coordination number nine (Figure 2). Sm1 atom is surrounded by seven carboxylic O atoms, one S atom ( S 1 ), and one O of a coordinated water molecule. Sm 2 is bound to four O atoms from water molecules and five carboxylic O atoms arising from two different ligands (those containing the non-coordinated S2 and S3 atoms). Sm1-S1 distance is $3.130(1) \AA$, which is close to the values found in similar structures containing $\mathrm{Ln}(\mathrm{III})$ ions and thiol-type S atoms (Table S2).

Figure 2. Perspective drawing of $\mathbf{1}$ showing the atom labels. Thermal ellipsoids are plotted at the $50 \%$ probability level. Hydrogen atoms and crystallization water molecules are omitted for clarity. Color code: Sm, orange; C, light grey; O, red; S, yellow. The symmetry-related atoms were obtained by applying the symmetry codes ${ }^{\text {i }} 1-x,-y, 1-z ;{ }^{\text {ii }}-x, 1-y,-z ;{ }^{\text {iii }} 1-x, 1-y,-z$; ${ }^{\text {iv }}-1+x,+y,+z$.

Table 3. Bond lengths ( $\AA$ ) around central atom for $\mathbf{1}$ and 2.

| 1 |  |  |  | 2 |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

| ${ }^{\text {i }} 1-\mathrm{x},-\mathrm{y}, 1-\mathrm{z} ;{ }^{\text {ii }}-\mathrm{x}, 1-\mathrm{y},-\mathrm{z}$; ${ }^{\text {iii }} 1-\mathrm{x}, 1-\mathrm{y},-\mathrm{z}$; ${ }^{\text {iv }}-1+\mathrm{x},+\mathrm{y},+\mathrm{z}$ |  |  |  | $\begin{aligned} & { }^{\mathrm{i}} 1-\mathrm{x}, 2-\mathrm{y}, 1-\mathrm{z} ;{ }^{\mathrm{ii}}-\mathrm{x}, 2-\mathrm{y}, 1-\mathrm{z} ;{ }^{\text {iii }} \mathrm{x},-1+\mathrm{y}, 1+\mathrm{z} ;{ }^{\text {iv }}-\mathrm{x}, 1-\mathrm{y} \text {, } \\ & 2-\mathrm{z} \end{aligned}$ |  |  |  |

In both Sm ions, polyhedra can be described as a tricapped trigonal prism (JTCTPR9) $[82,83]$. For Sm1, the tricapped trigonal prism is quite irregular with O1, O3, O5, O9, O6i, and O10i as the vertices of the prism (average distance $2.419 \AA$ ), and OW1, O9i, and S1 in the apices (average distance $2.714 \AA$ ). In the case of Sm2, O2W, O3W, O4W, O11, O7iii, and O12ii conform the prism (average distance $2.467 \AA$ ), while O5W, O7iv, and O8iii occupy the apical positions (average distance $2.473 \AA$ ). This is shown in Figure S4.

It is interesting to view the connection between $\mathrm{Sm}(\mathrm{III})$ ions provided by the ligand (Scheme 1). Three non-equivalent ligands are present in the structure. Tda residue containing S1 does not link Sm ions. On the contrary, it is only bound to Sm 1 as a tridentate ligand, generating two O atoms ( O 2 and O 6 ) that do not participate in the coordination. The ligand with S2 connects four Sm ions in a monodentate fashion. The third ligand (with S3) connects three Sm(III) ions, bis-monodentate towards Sm1 and bidentate towards Sm2.

Scheme 1. Coordination modes of tda in compound $\mathbf{1}$ (left) and in previously reported structures [ $\mathrm{Ln}_{2}(\mathrm{tda})_{3}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}$ ] (right) [59-61].

The coordinative versatility of this ligand provokes the formation of thick sheets in the bc plane (Figure 3). Sm1 polyhedra are disposed of in couples sharing an edge through carboxylate groups of ligands with S2 and S3. In contrast, the Sm2 polyhedron shares an edge with an Sm1 polyhedron through O atoms from the third ligand (with S3).

Figure 3. Packing of $\mathbf{1}$ in the bc plane. Polyhedra of Sm 1 are colored orange, while Sm 2 ones are light blue. Hydrogen atoms and crystallization water molecules are omitted for clarity.

Crystallization water molecules occupy the free space between the sheets and are involved in H-bonds, in particular with the uncoordinated O atoms. This is shown in Figure S5.

Previously reported structures with formula $\left[\mathrm{Ln}_{2}(\mathrm{tda})_{3}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}\right]$ exhibit the identical molar ratio Ln:tda found in 1 and 2 [59-61]. They crystallize in the same triclinic space group $P \overline{1}$, contain two crystallographically non-equivalent Ln atoms, and also present a 2D structure. It is interesting to compare the Ln-S distances. They are 3.105 and $3.091 \AA$ for Dy [59,60], $3.105 \AA$ for $\operatorname{Eu}$ [61], $3.098 \AA$ for $G d[60], 3.122 \AA$ for $S m$ [59], and $3.099 \AA$ for Tb [60]. These values have not been considered as a bond distance, except in the Eu structure. Assuming that an Ln-S bond is present, Ln1 is coordinated by eight oxygen atoms (all of them from carboxylate groups) and one sulfur atom, and Ln2 is coordinated by nine O atoms, two of them from coordinated water molecules. From the ligand point of view, two coordination modes are present, as shown in Scheme 1.

### 3.4. Photophysical Studies

Figure 4 depicts the solid-state luminescence spectra of compound 2 upon direct excitation of $\mathrm{Eu}($ III $)$ ion at 394 nm , selected from the excitation spectrum and giving place to the characteristic emission profile of the intra-configuration emission of the metal ion. Eu (III) is, in general, a much more intense luminescence emitter than Sm(III) [84], accounting for compound $\mathbf{2}$ is a much more intense emitter than compound $\mathbf{1}$ (which is shown in Figure S6, together with the excitation spectra and the assignment for emission bands). The emission spectra of $\mathrm{Eu}(\mathrm{III})$ show the characteristic five main bands corresponding to the intra-configuration transitions ${ }^{5} \mathrm{D}_{0} \rightarrow{ }^{7} \mathrm{~F}_{\mathrm{J}}$, with $\mathrm{J}=0-4$. Noticeably, the truly forbidden transition ${ }^{5} \mathrm{D}_{0} \rightarrow{ }^{7} \mathrm{~F}_{0}$ is observed, even though with very low intensity. This band is probably associated with the less-symmetric Eu1 center (bound S1 atom) described in the crystal structure. The presence of the S1 atom in one of the apices of the tricapped trigonal prism excludes the existence of a mirror plane orthogonal to the main symmetry axis $[85,86]$. Indeed, in the $\left[\mathrm{Eu}(\mathrm{oda})_{3}\right]^{3-}$ complex, with all positions of the tricapped trigonal prism occupied O atoms and similar Eu-O bond distances, this forbidden band is not observed [18]. The magnetic dipole transition ${ }^{5} \mathrm{D}_{0} \rightarrow{ }^{7} \mathrm{~F}_{1}$ band shows in compound 2 an intense degenerated profile, in line with the rotational symmetry in the coordination geometry. Furthermore, the ${ }^{5} \mathrm{D}_{0} \rightarrow{ }^{7} \mathrm{~F}_{2}$ hypersensitive band is 1.3 times more intense than the magnetic dipole transition ${ }^{5} \mathrm{D}_{0} \rightarrow{ }^{7} \mathrm{~F}_{1}$ band. Noticeably, in the previously reported
complex $\left[\mathrm{Eu}_{2}(\mathrm{tda})_{3}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}\right]$, with just two coordinated water molecules coordinated to one of the emissive centers, the ${ }^{5} \mathrm{D}_{0} \rightarrow{ }^{7} \mathrm{~F}_{2}$ hypersensitive band shows an intensity more than three times higher than that of the ${ }^{5} \mathrm{D}_{0} \rightarrow{ }^{7} \mathrm{~F}_{1}$ band [61]. The presence of four coordinated water molecules in 2 accounts for the lower comparative observed intensity of the ${ }^{5} \mathrm{D}_{0} \rightarrow{ }^{7} \mathrm{~F}_{2}$ band. Also in line with this, the behavior of compound $\mathbf{1}$ is also influenced by the presence of coordinated water molecules, which diminishes the emissive behavior of Sm ion, relative to that observed for $\left[\mathrm{Sm}_{2}(\mathrm{tda})_{3}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}\right]$ [59] (Figure S6).

Figure 4. (Left): solid-state excitation spectra. (Right): emission spectra of compound 2 excited at 394 nm . Transitions assigned to each band are also shown. An inset is included for more detail on the ${ }^{5} \mathrm{D}_{0} \rightarrow{ }^{7} \mathrm{~F}_{0}$ band.

## 4. Conclusions

The chemistry of thiodiacetato with the lanthanide ions Sm (III) and Eu (III) has been explored. First, the solution behavior of this system has been studied, and some light has been shed on the formed species, considering also previously reported inconclusive findings. Starting from this knowledge, two new compounds have been obtained and fully characterized, showing the versatility of the thiodiacetato ligand, which can either chelate or connect the lanthanide(III) centers. The solid-state optical properties of the two compounds were studied, the $\mathrm{Eu}(\mathrm{III})$ compound resulting in a better luminescence emitter material.

#### Abstract

The effect of different pendant arms on the structural chemistry of the 1,4,7-trithia-10-aza-cyclododecane ([12]aneNS $\mathrm{S}_{3}$ ) macrocycle is discussed in relation to the coordination chemistry of all known functionalized derivatives of $[12] a n e \mathrm{NS}_{3}$, which have been structurally characterized.

Keywords: 1,4,7-trithia-10-aza-cyclododecane; macrocyclic ligands; pendant arms; conformation

## 1. Introduction

1,4,7-Trithia-10-aza-cyclododecane ([12]aneNS ${ }_{3}$ ( L in Figure 1) is a well-known 12-membered mixed thia-aza macrocycle featuring a $\mathrm{NS}_{3}$ donor set suitable for coordination to soft metal ions [1-15]. It has been extensively functionalized at the secondary nitrogen atom to afford pendant arm derivatives for different purposes: fluorescent materials and chemosensors for heavy metal ions [3,4,9-11], highly selective heteroditopic ionophores for simultaneous binding, extraction and transport of both the cationic and anionic moieties of toxic and / or precious transition metal salts [12,13], crystal engineering in the preparation of coordination polymers [5,8,12], tuning of the coordination environment around soft metal ions [2,6,7,15], and development of new synthetic methods of mixed-donor thiacrown ethers [1,14]. All structurally characterized pendant arm derivatives of [12]aneNS $3_{3}(\mathbf{L})$ are reported in Figure 1, including both metal-coordinated ligands (drawn in black) and free ligands (drawn in red). Of note, no X-ray crystal structure of $\mathbf{L}$ is known, and $\mathbf{L 7}$ is the only derivative of [12]aneNS ${ }_{3}$ for which the X-ray crystal structure is known together with some of its transition metal coordination compounds. In this paper, we report the X-ray crystal structure of $\mathbf{L 1 2}$ and the synthesis and structural characterization of two new $\mathbf{L}$ derivatives, i.e., $\mathbf{L} 20$ and $\mathbf{L 2 1} \cdot \mathrm{CHCl}_{3}$ (Figure 2). The two new derivatives of $\mathbf{L}$ were chosen to favor intermolecular interactions involving the functional groups in the pendant arm and the donor atoms from the macrocyclic moiety. In particular, in the case of L20, we wanted to explore the possibility of intermolecular halogen bonds (XBs) formation involving the $S$ donor atoms of the macrocyclic moiety and the effects on its conformation. The three new crystal structures are discussed and compared with those already known in order to identify particular trends in the conformational changes in the macrocyclic moiety upon
coordination with metal ions, and the geometrical effects induced by pendant arms bearing additional functionalities.

## 2. Materials and Methods

### 2.1. Materials and Methods

1,4,7-Trithia-10-aza-cyclododecane ([12]aneNS $3_{3}$ ) [11] and $\mathbf{L 1 2}$ were synthesized according to the procedure reported in the literature [9]. Reagents and solvents were used that were purchased from Aldrich. Elemental analyses were performed with an EA1108 CHNS-O Fisons instrument ( $T=1000^{\circ} \mathrm{C}$ ). The ${ }^{1} \mathrm{H}$ - and ${ }^{13} \mathrm{C}$-NMR spectra were determined on a Bruker Avance 600 MHz spectrometer. The mass spectra were recorded on a triple quadrupole QqQ Varian 310-MS mass spectrometer by using the atmospheric pressure ESI technique. All sample solutions were infused into the ESI source with a programmable syringe pump ( $1.50 \mathrm{~mL} / \mathrm{h}$ constant flow rate). A dwell time of 14 s was used, and the spectra were accumulated for at least 10 min to increase the signal-to-noise ratio. The mass spectra were recorded in the $m / z 100-1000$ range. The following scan parameters were chosen [16]: needle voltage 3500 V , shield 800 V , source temperature $60^{\circ} \mathrm{C}$, drying gas pressure 20 psi , nebulizing gas pressure 20 psi , detector voltage 1450 V , and drying gas temperature $110^{\circ} \mathrm{C}$. The isotopic patterns of the measured peaks in the mass spectra were analyzed using the mMass 5.5 .0 software package [17]. All mass values were indicated as monoisotopic masses, which were computed as the sum of the masses of the primary isotope of each atom in the molecule (note that the monoisotopic mass may differ from the nominal molecular mass).

### 2.2. X-ray Diffraction Analyses

Only special features are noted here. Crystallographic data are reported in Table S1 in the Supplementary Materials. Single-crystal X-ray diffraction (SC-XRD) data for compound L12 were collected at 150 K on a Bruker SMART 1000 diffractometer using MoK $\alpha$ radiation. The data were indexed and processed using Bruker SAINT and SMART $[18,19]$. The structure was solved by the SIR92 [20] solution program using direct methods. SC-XRD data for compound L20 were collected at 293 K on an Agilent SuperNova diffractometer equipped with an Eos detector using MoK $\alpha$ radiation. The data were indexed and processed using CrysalisPro [21] and the structure was solved by SHELXT [22] using dual-space methods. SC-XRD data for the compound $\mathbf{L 2 1} \cdot \mathrm{CHCl}_{3}$ were collected at 293 K on a Bruker APEX II CCD diffractometer using MoK $\alpha$ radiation. The data were indexed and processed using Bruker SAINT [18]. The structure was solved by SIR92 [20] using direct methods. The models were refined with ShelXL [23] using full-matrix least-squares minimization on $F^{2}$. All non-hydrogen atoms were anisotropically refined. Hydrogen atom positions were geometrically calculated and refined using the riding model. Olex2, version 1.5 [24], was used as the graphical interface. For the compound $\mathbf{L 2 1} \cdot \mathrm{CHCl}_{3}$, the solvent molecule was disordered and modelled over two sites with statistically the same occupancy [0.49(1) and $0.51(1)$, respectively]. Complete crystallographic data for the structure of compounds L12, $\mathbf{L 2 0}$, and $\mathbf{L 2 1} \cdot \mathrm{CHCl}_{3}$ were deposited in CIF format at the Cambridge Crystallographic Data Center (CCDC) with deposition numbers 2248158-2248160, respectively.

### 2.3. Synthesis of $\mathbf{L 2 0}$

A mixture of 1,4,7-trithia-10-aza-cyclododecane ( $0.178 \mathrm{~g}, 0.790 \mathrm{mmol}$ ), 2-bromobenzyl bromide ( 0.199 g 0.790 mmol ), and $\mathrm{K}_{2} \mathrm{CO}_{3}(0.37 \mathrm{~g}, 2.6 \mathrm{mmol})$ in dry $\mathrm{MeCN}(50 \mathrm{~mL})$ was heated to reflux for 96 h under a dry $\mathrm{N}_{2}$ atmosphere. The solid was filtered off and the solvent was removed under reduced pressure. The residue was dissolved in dichloromethane (DCM) and washed with distilled water. The organic phase was dried over $\mathrm{Na}_{2} \mathrm{SO}_{4}$ and the solvent was removed under reduced pressure. The residue was purified by flash chromatography (silica) using $\mathrm{DCM} / \mathrm{MeOH}(10: 0.3, v / v)$ as eluent to give a pale-yellow solid ( $0.187 \mathrm{mg}, 0.63 \mathrm{mmol}$, $80 \%$ yield). Elemental analysis, Found (Calcd. for $\mathrm{C}_{15} \mathrm{H}_{22} \mathrm{BrNS}_{3}$ ): C, 45.68 (45.91); H, 5.58 (5.65); N, 3.71 (3.57); S, 24.42 (24.51)\%. M.p. $108{ }^{\circ} \mathrm{C} ;{ }^{1} \mathrm{H}-\mathrm{NMR}\left(\mathrm{CDCl}_{3}, 600 \mathrm{MHz}\right): \delta_{\mathrm{H}}$ (ppm) 2.65-2.69 (m, 4H), 2.78-2.82 (m, 12H), 3.71 (s, 2H, NCH Nr ), $7.12(\mathrm{t}, J=7.1 \mathrm{~Hz}, 1 \mathrm{H})$, $7.29(\mathrm{t}, J=7.3 \mathrm{~Hz}, 1 \mathrm{H})$, and $7.54(\mathrm{~d}, J=7.5 \mathrm{~Hz}, 2 \mathrm{H}) ;{ }^{13} \mathrm{C}\left\{{ }^{1} \mathrm{H}\right\}-\mathrm{NMR}\left(\mathrm{CDCl}_{3}, 150 \mathrm{MHz}\right): \delta_{\mathrm{C}}(\mathrm{ppm})$ 25.90, 27.86, $28.49\left(\mathrm{CH}_{2} \mathrm{~S}\right), 51.86\left(\mathrm{CH}_{2} \mathrm{~N}\right), 59.55\left(\mathrm{NCH}_{2} \mathrm{Ar}\right), 124.38,127.41,129.70,130.69,132.85$, and 137.88 (aromatic carbons); and ESI-MS(+): $m / z=393[\mathrm{M}+\mathrm{H}]^{+}$. The crystals of $\mathbf{L 2 0}$ suitable for an X-ray diffraction analysis were grown from a DCM solution by diffusion of $\mathrm{Et}_{2} \mathrm{O}$ vapor.

### 2.4. Synthesis of $\mathbf{L 2 1}$

A weighted amount of 2-hydroxy-5-nitrobenzyl bromide ( $0.170 \mathrm{~g}, 0.740 \mathrm{mmol}$ ) was added to a solution of 1,4,7-trithia-10-aza-cyclododecane ( $0.150 \mathrm{~g}, 0.670 \mathrm{mmol}$ ) and $\mathrm{K}_{2} \mathrm{CO}_{3}$ $(0.460 \mathrm{~g}, 3.33 \mathrm{mmol})$ in dry $\mathrm{MeCN}(20 \mathrm{~mL})$. The reaction mixture was heated under nitrogen at $80^{\circ} \mathrm{C}$ for 24 h and then for 24 h at room temperature. The solid was filtered off, and the solvent was removed under reduced pressure to give a yellow solid ( $0.170 \mathrm{mg}, 0.45 \mathrm{mmol}, 68 \%$ yield). Elemental analysis, Found (Calcd. for $\mathbf{C}_{15} \mathbf{H}_{22} \mathbf{N}_{2} \mathbf{O}_{3} \mathbf{S}_{3}$ ): C, 48.51 (48.10); $\mathrm{H}, 6.12$ (5.92); N, 7.48 (7.48); S, 25.91 (25.68)\%. M.p. $175{ }^{\circ} \mathrm{C}$; ${ }^{1} \mathrm{H}-\mathrm{NMR}\left(\mathrm{CDCl}_{3} / \mathrm{CD}_{3} \mathrm{CN}, 600 \mathrm{MHz}\right): \delta_{\mathrm{H}}(\mathrm{ppm}) 2.68$ $(\mathrm{m}, 4 \mathrm{H}), 2.76(\mathrm{~m}, 8 \mathrm{H}), 2.81(\mathrm{~m}, 4 \mathrm{H}), 3.71\left(\mathrm{~s}, 2 \mathrm{H}, \mathrm{NCH}_{2} \mathrm{Ar}\right), 6.56(\mathrm{~d}, J=9.2 \mathrm{~Hz}, 1 \mathrm{H}), 7.91$ (dd, $J=3.0 \mathrm{~Hz}, 1 \mathrm{H})$, and $8.05(\mathrm{~d}, J=2.8 \mathrm{~Hz}, 1 \mathrm{H}) ;{ }^{13} \mathrm{C}\left\{{ }^{1} \mathrm{H}\right\}-\mathrm{NMR}\left(\mathrm{CDCl}_{3} / \mathrm{CD}_{3} \mathrm{CN}, 150 \mathrm{MHz}\right): \delta_{\mathrm{C}}$ (ppm) 26.5, 29.2, 29.4(CH2S), $52.5\left(\mathrm{CH}_{2} \mathrm{~N}\right), 56.1\left(\mathrm{NCH}_{2} \mathrm{Ar}\right), 118.7,126.2,126.9,127.4,136.7$, and 172.6 (aromatic carbons); and ESI-MS(+): $m / z=375[\mathrm{M}+\mathrm{H}]^{+}$. The crystals of $\mathbf{L} 21 \cdot \mathrm{CHCl}_{3}$ suitable for an X-ray diffraction analysis were grown from a $\mathrm{CHCl}_{3}$ solution.

## 3. Results and Discussion

The X-ray crystal structure of L12 is characterized by the formation of dimeric arrangements via $\mathrm{N} \cdots \mathrm{H}-\mathrm{O}$ hydrogen bonds involving the -OH group and the aromatic N atom from the pendant arms of two symmetry-related ligand units (Figure 3). $\pi-\pi$ Stacking interactions between the quinoline moieties of adjacent slipped dimers (centroid-centroid distance: $3.77 \AA$ ) generate a staircase architecture along the $b$-axis as shown in Figure S1 in the Supplementary Materials.

In L12, the macrocyclic unit adopts a square-shaped conformation with the four donor atoms occupying the corners. A useful convention to describe the different conformations that an aliphatic macrocycle can adopt is that of Dale [25], and it is based on the sequence of torsion angles around the macrocycle ring, which normally are classified as either anti $\left(\cong 180^{\circ}\right)$ or gauche $\left(\cong 60^{\circ}\right)$. According to the Dale convention, a generic conformation is determined by the number of bonds between each corner in the macrocycle (a corner is the atom at which two gauche torsion angles intersect). Considering the sequence of the torsion angles in L12 (Table 1), four corners in the [12]aneNS $3_{3}$ unit are present at the N and S donor atoms. Each pair of corners is separated by one $-\mathrm{N}-\mathrm{CH}_{2}-\mathrm{CH}_{2}-\mathrm{S}-$ or $-\mathrm{S}-\mathrm{CH}_{2}-\mathrm{CH}_{2}-\mathrm{S}-$ side-moiety unit featuring an anti-torsion angle at the $\mathrm{C}-\mathrm{C}$ bond. Therefore, the conformation adopted by the macrocyclic unit in L12 is [3333], according to the Dale convention, with the lone pairs (LPs) of electrons on the donor atoms in exo-dentate positions (i.e., pointing out of the ring cavity).

Figure 3. (a) View of the asymmetric unit of L12 with the atom-labelling scheme adopted. Hydrogen atoms are omitted for clarity. Displacement ellipsoids are drawn at $50 \%$ probability level; (b) H-bonded dimeric arrangement found in L12 with the numbering scheme adopted. Only interacting hydrogen atoms are shown for clarity. $\mathrm{N} 23 \cdots \mathrm{O} 24^{\mathrm{i}}=2.8514(6) \AA ; \mathrm{O} 24^{\mathrm{i}}-\mathrm{H} 24^{\mathrm{i}} \cdots \mathrm{N} 23=135^{\circ}$; and symmetry operation: $i=-x,-y, 2-z$. For selected bond lengths $(\AA)$ and angles $\left({ }^{\circ}\right)$, see Table S2 in the Supplementary Materials.

Table 1. Torsion angles $\left({ }^{\circ}\right)$ for the [12]aneNS $3_{3}$ moieties in $\mathbf{L 1 2 ,} \mathbf{L 2 0}$, and $\mathbf{L 2 1} \cdot \mathrm{CHCl}_{3}$ with the Dale conformations in bracket squares (gauche torsion angles in red).

This type of conformation with exo-dentate donor atoms positioned at the corners is very common in medium and large aliphatic thioether macrocycles, as demonstrated by diffraction studies [26-28]: an anti-torsion angle at the $\mathrm{C}-\mathrm{C}$ bond in the $-\mathrm{S}-\mathrm{CH}_{2}-\mathrm{CH}_{2}-\mathrm{S}$ - units is preferred as a consequence of the repulsive 1,4-interaction between the sulfur LPs in a gauche arrangement [29]. On the other hand, a gauche torsion angle at the $\mathrm{C}-\mathrm{S}$ bond in a $-\mathrm{CH}_{2}-\mathrm{CH}_{2}-\mathrm{S}-\mathrm{CH}_{2}-$ sequence is not disfavored by the 1,4-interactions of the methylene protons, which lie beyond the sum of the corresponding van der Waals radii [30]. An opposite trend is observed in oxa-macrocycles due to the different $\mathrm{C}-\mathrm{O}$ bond length and covalent radius of the donor atom [31].

In general, and in the specific case of L12, metal complexation or the involvement of one of the donor atoms of the [12]aneNS ${ }_{3}$ unit in interactions with functionalities present in the pendant arms can strongly affect the conformation adopted by the macrocyclic unit in the solid state.

In fact, the X-ray crystal structure of $\mathbf{L 2 0}$ is also characterized by dimeric arrangements via $\mathrm{C}-\mathrm{Br} \cdots \mathrm{S}$ halogen bonds (XBs) involving one of the S donors from the macrocyclic unit as an XB acceptor, and the Br atom on the benzylic pendant arm as an XB donor (Figure 4).

(a)

Figure 4. Cont.

Figure 4. (a) View of the asymmetric unit of $\mathbf{L 2 0}$ with the atom-labelling scheme adopted. Hydrogen atoms have been omitted for clarity. Displacement ellipsoids are drawn at $50 \%$ probability level; (b) X-bonded dimeric arrangement found in $\mathbf{L 2 0}$ with the numbering scheme adopted. $\mathrm{S} 10 \cdots \mathrm{Br} 20^{\mathrm{i}}=3.5030(3) \AA ; \mathrm{C} 19-\mathrm{Br} 20 \cdots \mathrm{~S} 10^{\mathrm{i}}=163.6(1)^{\circ}$; and symmetry operation: $\mathrm{i}=-\mathrm{x}, 1-\mathrm{y},-\mathrm{z}$. For selected bond lengths $(\AA)$ and angles $\left({ }^{\circ}\right)$, see Table S3 in the Supplementary Materials.

Due to this intermolecular interaction, the macrocyclic unit assumes a [11334] conformation as five corners can be identified in the cyclic structure (three consecutive at the atoms C2, C3, and S4, and the other two at S7 and S10, Table 1). Compared to L12, anti-torsion angles in L 20 remain at the $\mathrm{C}-\mathrm{C}$ bonds in the sequencies $\mathrm{S} 4-\mathrm{C} 5-\mathrm{C} 6-\mathrm{S} 7$, S7-C8-C9-S10, and S10-C11-C12-N1 (Table 1), while the torsion angles at the C2-C3 and $\mathrm{C} 12-\mathrm{N} 1$ bonds in the sequences $\mathrm{N} 1-\mathrm{C} 2-\mathrm{C} 3-\mathrm{S} 4$ and $\mathrm{C} 11-\mathrm{C} 12-\mathrm{N} 1-\mathrm{C} 2$ adopt a gauche and an anti-conformation, respectively (vice versa in the case of L12, Table 1). Presumably, the pulling effect of the bromine atom on the sulfur atom S10 in forming the $X B$ causes the torsion angle at one of the $\mathrm{C}-\mathrm{N}$ to change from a gauche to an anti-conformation, and the torsion angle at the $\mathrm{C} 2-\mathrm{C} 3$ bond to do the exact opposite.

This does not happen in the structure of $\mathbf{L 2 1} \cdot \mathrm{CHCl}_{3}$, in which it is the N atom from the macrocyclic unit that is involved in a weak intramolecular interaction with a functional group in the pendant arm. In fact, the conformation adopted by the [12]aneNS $3_{3}$ unit in $\mathbf{L 2 1} \cdot \mathrm{CHCl}_{3}$ is again square-shaped [3333] with the exo-dentate donor atoms at the corners and $-\mathrm{N}-\mathrm{CH}_{2}-\mathrm{CH}_{2}-\mathrm{S}-$ or $-\mathrm{S}-\mathrm{CH}_{2}-\mathrm{CH}_{2}-\mathrm{S}-$ sequences with anti-torsion angles at the $\mathrm{C}-\mathrm{C}$ bonds at the sides (Table 1). In this compound, an intramolecular HB is formed between the hydroxyl - OH function and the tertiary N donor from the macrocyclic unit (Figure 5a), which keeps the exo-dentate orientation of the LP in the HB interaction. Furthermore, dimeric arrangements are determined by $\mathrm{C}-\mathrm{H} \cdots \mathrm{OHB}$ involving one oxygen atom from the nitro group and one benzylic hydrogen atom (Figure 5b).

Figure 5. (a) View of the asymmetric unit in $\mathbf{L 2 1} \cdot \mathrm{CHCl}_{3}$ with the atom-labelling scheme adopted. Displacement ellipsoids are drawn at $50 \%$ probability level. Hydrogen atoms and the co-crystallized $\mathrm{CHCl}_{3}$ molecule are omitted for clarity; (b) H-bonded dimeric arrangement found in $\mathbf{L 2 1} \cdot \mathrm{CHCl}_{3}$. Only interacting hydrogen atoms are shown for clarity. $\mathrm{N} 1 \cdots \mathrm{O} 20=2.612(3) ; \mathrm{N} 1 \cdots \mathrm{H} 20=1.90(3) \AA$; $\mathrm{O} 20-\mathrm{H} 20 \cdots \mathrm{~N} 1=150(3)^{\circ} ; \mathrm{C} 13-\mathrm{O} 23^{\mathrm{i}}=3.354(3) \AA$; and symmetry operation: $\mathrm{i}=1-x, 2-y, 2-z$. For selected bond lengths ( $\AA$ ) and angles $\left({ }^{\circ}\right)$, see Table $S 4$ in the Supplementary Materials.

A survey in the CSD (accessed on 13 January 2023) reveals a total of 31 X-ray crystal structures of [12]aneNS ${ }_{3}(\mathbf{L})$ derivatives bearing functionalized pendant arms being reported either as free ligands or as metal complexes. The comparative analysis of the conformations assumed by the macrocyclic framework in the crystallographically independent 43 units (Table S5 in the Supplementary Materials) in terms of Dale notation shows that all reported free ligands (8 independent units) feature the [3333] conformation with the exo-dentate donor atoms at the corners (black asterisks in Figure 6a) which is in line with what is found in the structures of $\mathbf{L 1 2}$ and $\mathbf{L 2 1} \cdot \mathrm{CHCl}_{3}$. The only exception is represented by the structure of $\mathbf{L 2 0}$ mentioned above, and by the conformation assumed by the macrocycle in its bromide salt [HL]Br$\cdot 2 \mathrm{H}_{2} \mathrm{O}$ [1]. In this compound, the macrocycle is protonated at the secondary nitrogen atom and it assumes an unusual [84] (Table S5) conformation with only two corners, both at the carbon atoms, due to the intramolecular $\mathrm{N}-\mathrm{H} \cdots \mathrm{S}$ HB involving the sulfur atom in front of the protonated N donor.

[3333](33)

$\begin{array}{lll}*[31143](1) & *[11433](1) & *[34113](2) \\ *[11334](2) & *[33114](1) & *[11334](\text { L20 })\end{array}$

Figure 6. Schematic representation of the conformations adopted by the [12]ane $\mathrm{NS}_{3}(\mathbf{L})$ macrocyclic moiety in the 31 X-ray crystal structures ( 43 independent units) retrieved from the CSD (Table S5 in the Supplementary Materials) featuring $\mathbf{L}$ derivatives (Figure 1) and their metal complexes. Asterisks indicate the corners in the various conformations according to the Dale notation. (a) Corner positions observed in [3333] conformations: black asterisks refer to the corner positions observed in free ligands, while red and green asterisks identify the corner positions observed in ligands coordinated to metal centers, and numbers in round brackets represent the overall number of independent units having the [3333] conformation; (b) corner positions in the alternative conformations observed in metal complexes of $\mathbf{L}$ derivatives, with each type of conformation identified by a different color of asterisk. The [84] conformation is not represented. To determine the number of bonds between each pair of corners and thereby assign the Dale notation to each conformation observed, start from the first corner to the left of the N atom as shown in the picture and proceed clockwise. This method was chosen to best illustrate the differences between conformations. The Dale notation is conventionally defined with the low numbers (i.e., the shortest edges) specified first, disregarding clockwise/anti-clockwise direction and crystallographic symmetries. In this way, all the conformations in Figure 6b would be assigned as [11334].

Among the remaining structures in which the macrocyclic moiety is involved in metal coordination, 25 independent units still display the macrocyclic moiety in a [3333] conformation with the corners located on carbon atoms and the donor atoms on - $\mathrm{CH}_{2}-\mathrm{CH}_{2}-$ $\mathrm{E}-\mathrm{CH}_{2}-$ (red asterisks in Figure 6a) or $-\mathrm{CH}_{2}-\mathrm{E}-\mathrm{CH}_{2}-\mathrm{CH}_{2}-$ (green asterisks in Figure 6a, counting clockwise from the first corner to the left of the N atom as shown in Figure 6) side edges of the square-shaped conformation ( $\mathrm{E}=\mathrm{N}$ or S ). A small number of compounds feature a conformation of the metal-coordinated macrocyclic unit in which three corners are located on three consecutive atoms including a $S$ atom in the middle (purple, cyan, green, red, and brown asterisks in Figure 6b, see Table S5). Only in the case of L20 does the sequence of three consecutive corners feature a $S$ atom at the end of the three consecutive atoms involved (yellow asterisks in Figure 6b). Interestingly, no conformations with three consecutive corners involving N as one of the three consecutive atoms are known. Finally, only two structures are known in which the macrocyclic framework adopts a [84] conformation featuring only two corners (both at the same carbon atoms, Table S5), namely $[\mathrm{HL}] \mathrm{Br} \cdot 2 \mathrm{H}_{2} \mathrm{O}[1]$ and $[\mathrm{CuCl}(\mathrm{L} 14)] \mathrm{CuCl}_{4}[12]$.

## 4. Conclusions

The extent to which a macrocyclic ligand must pre-organize its conformation prior to complexation is one of the structural factors that can strongly affect the stability of the resulting metal complexes. For some macrocycles, the most stable conformation in the free state is not the most suitable to bind the metal ion and some changes are necessary to satisfy the stereochemical requirements of the complexation process. Herein, we have analyzed the conformation adopted in the solid state by the [12]aneNS $3_{3}$ macrocyclic ring in
all its functionalized pendant arm derivatives, both as free ligands and as metal complexes. The derivatives of this 12-membered tetradentate $\mathrm{NS}_{3}$ macrocycle in their free state adopt a [3333] conformation, regardless of the nature of the functional groups in the pendant arms, with all 4 donor atoms at the corners of a square-shaped structure with the lone pairs in exo-dentate positions. This is also confirmed by the X-ray crystal structures of L 12 and $\mathbf{L 2 1} \cdot \mathrm{CHCl}_{3}$ presented herein. Therefore, upon complexation, a drastic conformational change is required to bring the lone pairs on the donor atoms into endo-dentate arrangements to maximize coordination to the metal ion. The most commonly observed conformation of the [12]aneNS $\mathrm{S}_{3}$ moiety bound to metal ions is still of the type [3333], but the donor atoms sacrifice their preferred corner positions and each becomes part of a "side" of the square-shaped structure, with each side made up of a sequence of gauche-anti-gauche torsion angles. In very few reported cases, endo-dentate arrangements of the donor atoms in the [12]aneNS $3_{3}$ moiety are reached upon coordination by assuming conformations that are different from the [3333]. These conformations of the type [33114] (or related ones by cyclic permutations of the corner positions, see Figure 6 and Figure S2 in the Supplementary Materials) all feature three consecutive corners, i.e., three consecutive atoms at which two gauche torsion angles intersect, of which a S atom is always in the middle. The other three donor atoms (two S and one N ) are not in corner positions. A similar conformation of the [12]aneNS $3_{3}$ moiety, but with a $S$ donor atom being a terminal corner in the sequence of three consecutive ones (Figure 6b), has been observed in the structure of the free ligand L20, and it is determined by an intermolecular $\mathrm{C}-\mathrm{Br} \cdots \mathrm{S}$ halogen bond. In $\mathbf{L 2 0}$, the conformation adopted by the macrocyclic unit is [11334] and not [3333] as normally observed; the three S donor atoms are all in corner positions while the N donor atom is not and is characterized by an endo-dentate orientation of its lone pair. We conclude that this is the only case in which the functional group in the pendant arm affects the conformation assumed by the [12]ane $\mathrm{NS}_{3}$ macrocyclic moiety due to a direct intermolecular interaction with one of the $S$ donor atoms. Our results suggest that in order to have a conformation other than [3333] for the macrocyclic moiety of uncoordinated pendant arm derivatives of $\mathbf{L}$, rather than considering intramolecular HBs involving the N atom and HB donors in the pendant arms (see the structure of $\mathbf{L 2 1} \cdot \mathrm{CHCl}_{3}$ ), it is more convenient to look for functionalities that can interact with the S donors of the macrocyclic moiety.

#### Abstract

A tripodal anion receptor has been obtained by an easy and fast single-reaction synthesis from commercial reagents. The three ligand arms-bearing aromatic groups able to form anion $-\pi$ interactions define ligand clefts where large anions, such as perchlorate and perrhenate, are included We report here the synthesis of the ligand, its acid/base properties in an aqueous solution which has been used to direct the synthesis of anion complexes, and the crystal structure of the free ligand and its anion complexes $\mathrm{H}_{3} \mathrm{~L}\left(\mathrm{ClO}_{4}\right)_{2} \cdot \mathrm{H}_{2} \mathrm{O}$ and $\mathrm{H}_{3} \mathrm{~L}\left(\mathrm{ReO}_{4}\right)_{2}$.

Keywords: anion complexes; perrhenate; perchlorate; anion- $\pi$; cleft system

## 1. Introduction

The design and synthesis of receptors for anionic species have attracted the interest of synthetic chemists since the dawn of supramolecular chemistry. Receptors of increasing complexity have been constructed, from simple linear or branched to more complex macrocyclic and macropolycyclic (cage-like) molecules, which have substantially contributed to forming the general concept that, with few exceptions, more structured and preorganized receptors form more stable anion complexes and provide more efficient molecular recognition processes. Indeed, macrocyclic and macropolycyclic molecules have proved to be very efficient anion receptors. Regrettably, they have the drawback that they often require lengthy and onerous synthetic procedures [1-11].

In this paper, we turn our attention toward a receptor that is easily accessible (from a synthetic point of view) and that, despite its open-chain structure, contains preorganized molecular clefts in which anions can be efficiently housed. This receptor (HL, Figure 1) is a tripodal molecule resembling the tetramine tren (tris(2-aminoethyl)amine), whose protonated species are known to form stable complexes with anions [12], but have a more rigid structure caused by the presence of three aromatic groups. HL can be easily prepared via a single-reaction functionalization of the commercial product N1,N1-bis(pyridin-2-ylmethyl)ethane-1,2-diamine with 6-amino-3,4-dihydro-3-methyl- 5-nitroso-4-oxo-pyrimidine (Figure 1 and Section 2).

In an acidic solution, HL undergoes protonation forming ammonium groups able to bind anions via electrostatic attraction and the formation of salt bridges (hydrogen bonds between oppositely charged species). In addition, HL can also use its aromatic groups to bind anions via anion $-\pi$ interactions. In particular, the pyrimidine inserted into the receptor was chosen precisely for this reason: being highly electron-poor, it has a marked tendency to form anion $-\pi$ interactions, a characteristic confirmed by the crystal structures of several anion complexes with receptors containing this group [13-17]. Moreover, protonated pyridine groups have a non-negligible ability to form anion- $\pi$ interactions [18-28].

In this paper, we perform a solid-state analysis of the anion-binding characteristics of $\mathrm{H}_{3} \mathrm{~L}^{2+}$, the diprotonated form of HL , toward the monocharged tetrahedral $\mathrm{ClO}_{4}^{-}$and $\mathrm{ReO}_{4}{ }^{-}$anions, observed in the crystal structures of $\mathrm{H}_{3} \mathrm{~L}\left(\mathrm{ClO}_{4}\right)_{2} \cdot \mathrm{H}_{2} \mathrm{O}$ and $\mathrm{H}_{3} \mathrm{~L}\left(\mathrm{ReO}_{4}\right)_{2}$.

These anions were chosen because, in addition to their technological, biomedical, and environmental interest [29-37], they are challenging targets for binding as they have low charge density and poor hydrogen bonding ability $[38,39]$. Nevertheless, binding and even recognition of these anions was achieved in some cases, yet the receptors used were often more structurally complex and laborious to prepare [38-41].

## 2. Materials and Methods

### 2.1. General

All starting materials were high-purity compounds purchased from commercial sources and were used without further purification. Compound 6-amino-3,4-dihydro-3-methyl-2-methoxy-5-nitroso-4-oxopyrimidine (2) was prepared according to a reported procedure [42]. Elemental analysis was performed with a FlashSmart ${ }^{\mathrm{TM}}$ Elemental Analyzer (Thermo Fisher Scientific, Monza, Italy).

### 2.2. Synthesis of $\mathrm{HL}\left(\mathrm{HL} \cdot \mathrm{EtOH} \cdot \mathrm{H}_{2} \mathrm{O}\right)$

HL was synthesized as schematically shown in Figure 1. 0.58 g ( 3.1 mmol ) of solid 2 was added in successive portions to a stirred solution of $1(0.60 \mathrm{~g}, 2.5 \mathrm{mmol})$ in methanol $\left(30 \mathrm{~cm}^{3}\right)$ at room temperature. After compound 2 was completely dissolved (about 90 min ), $0.5 \mathrm{~cm}^{3}$ of $37 \% \mathrm{NH}_{3}$ was added at room temperature to convert the excess of 2 into the insoluble 2,4-diamino-1-methyl-5-nitroso-6-oxopyrimidine derivative, and the resulting solution was left overnight at $4^{\circ} \mathrm{C}$. The suspension was then filtered and the solution was evaporated to dry under vacuum at room temperature to obtain HL as a deep purple solid compound that was recrystallized from ethanol. Yield $67 \%$. ${ }^{1} \mathrm{H}$ NMR $\left(\mathrm{D}_{2} \mathrm{O}, 400 \mathrm{MHz}\right) \delta$ $8.72(\mathrm{~d}, 2 \mathrm{H}), 8.54(\mathrm{t}, 2 \mathrm{H}), 8.10(\mathrm{~d}, 2 \mathrm{H}), 7.96(\mathrm{t}, 2 \mathrm{H}), 4.34(\mathrm{~s}, 4 \mathrm{H}), 3.87(\mathrm{t}, 2 \mathrm{H}), 3.40(\mathrm{~s}, 3 \mathrm{H}), 3.00$ $(\mathrm{t}, 2 \mathrm{H})$. Anal. calcd. for $\mathrm{C}_{21} \mathrm{H}_{30} \mathrm{~N}_{8} \mathrm{O}_{4}\left(\mathrm{HL} \cdot \mathrm{EtOH} \cdot \mathrm{H}_{2} \mathrm{O}\right)$ : C, $55.01 ; \mathrm{H}, 6.59 ; \mathrm{N}, 24.44$. Found: C, $54.34 ; \mathrm{H}, 6.52 ; \mathrm{N}, 24.37$. The crystals of this sample were suitable for X-ray.

### 2.3. Synthesis of $\mathrm{H}_{3} \mathrm{~L}\left(\mathrm{ClO}_{4}\right)_{2} \cdot \mathrm{H}_{2} \mathrm{O}$

$20 \mathrm{mg}(0.044 \mathrm{mmol})$ of $\mathrm{HL} \cdot \mathrm{EtOH} \cdot \mathrm{H}_{2} \mathrm{O}$ was dissolved in $5 \mathrm{~cm}^{3}$ of water and the pH of the solution was brought to about 2.5 by the addition of diluted $\mathrm{HClO}_{4}$. The crystals of $\mathrm{H}_{3} \mathrm{~L}\left(\mathrm{ClO}_{4}\right)_{2} \cdot \mathrm{H}_{2} \mathrm{O}$ suitable for X-ray analysis were obtained by slow evaporation of this solution at room temperature. The crystals were filtered and air-dried. Yield 47\%. Anal. calcd. for $\mathrm{C}_{19} \mathrm{H}_{26} \mathrm{~N}_{8} \mathrm{O}_{11} \mathrm{Cl}_{2}$ : C, 37.21; H, 4.27; N, 18.27. Found: C, 37.09; H, 4.31; N, 18.16.

### 2.4. Synthesis of $\mathrm{H}_{3} \mathrm{~L}\left(\mathrm{ReO}_{4}\right)_{2}$

$20 \mathrm{mg}(0.044 \mathrm{mmol})$ of $\mathrm{HL} \cdot \mathrm{EtOH} \cdot \mathrm{H}_{2} \mathrm{O}$ was dissolved in $5 \mathrm{~cm}^{3}$ of water and the pH of the solution was brought to about 2.5 by the addition of diluted HCl . A two-fold excess of $\mathrm{NaReO}_{4}$ was then added and the resulting solution was allowed to evaporate at room temperature to form the crystals of $\mathrm{H}_{3} \mathrm{~L}\left(\mathrm{ReO}_{4}\right)_{2}$ suitable for X-ray analysis. The crystals were filtered and air-dried. Yield $59 \%$. Anal. calcd. for $\mathrm{C}_{19} \mathrm{H}_{24} \mathrm{~N}_{8} \mathrm{O}_{10} \mathrm{Re}_{2}$ : C, 25.45; H, 2.70; N, 12.49. Found: C, 25.13; H, 2.78; N, 12.41.

### 2.5. Potentiometric Measurements

Ligand (HL) protonation constants were determined by means of potentiometric ( $\mathrm{pH}-$ metric) titrations in $0.1 \mathrm{M} \mathrm{NMe}_{4} \mathrm{Cl}$ aqueous solution at $298.1 \pm 0.1 \mathrm{~K}$ using an automated apparatus and a procedure previously described [43]. The acquisition of the emf data was performed with the computer program PASAT [44,45]. The combined electrode (Metrohm 6.0262.100, Metrohm, Herisau, Switzerland) was calibrated as a hydrogen-ion concentration probe by titration of known amounts of HCl with $\mathrm{CO}_{2}$-free NaOH solutions and by determining the equivalent point by Gran's method [46], which gives the standard potential, $\mathrm{E}^{\circ}$, and the ionic product of water $\left(\mathrm{p} K_{\mathrm{w}}=13.83(1)\right.$ in $0.1 \mathrm{M} \mathrm{NMe}_{4} \mathrm{Cl}$ at 298.1 K$)$. The stability constants were calculated from the potentiometric data by means of the computer program HYPERQUAD [47]. The concentration of HL was about $1 \times 10^{-3} \mathrm{M}$ in all experiments. The studied pH range was $2.0-11.5$. Three measurements were performed and used to determine the protonation constants. Titration curves and relative fittings are reported in Figure S1.

### 2.6. Spectroscopic Measurements

UV-vis absorption spectra were recorded at 298 K by using a Jasco V-670 spectrophotometer (Jasco Europe, Lecco, Italy). Ligand solution was [HL] $=2 \times 10^{-5} \mathrm{M}$. Spectra were recorded in the pH range $0.80-7.24$ (a) and $7.24-12.58$ (b). FT-IR spectra were recorded at room temperature on crystalline samples in attenuated total reflectance (ATR) mode with an IRAffinity-1S instrument (Shimadzu, Milan, Italy).

### 2.7. Single-Crystal X-ray Diffraction Analyses

Purple crystals of $\mathrm{HL} \cdot \mathrm{EtOH} \cdot \mathrm{H}_{2} \mathrm{O}$ and orange crystals of $\mathrm{H}_{3} \mathrm{~L}\left(\mathrm{ReO}_{4}\right)_{2}$ and $\mathrm{H}_{3} \mathrm{~L}\left(\mathrm{ClO}_{4}\right)_{2} \cdot \mathrm{H}_{2} \mathrm{O}$ were used for X-ray diffraction analysis. A summary of the crystallographic data is reported in Table 1. The integrated intensities were corrected for Lorentz and polarization effects and an empirical absorption correction was applied [48]. The structures were solved by direct methods (SHELXS-97) [49]. Refinements were performed by means of full-matrix least-squares using SHELXL Version 2014/7 [50]. All non-hydrogen atoms were anisotropically refined. Hydrogen atoms were usually introduced in a calculated position and their coordinates were refined according to the linked atoms. Two different conformations were found for the nitroso group in the perrhenate salt. Their population parameters were refined constraining their sum to $1(0.538 / 0.462$ at the end of refinement). The acidic hydrogen atoms and one water hydrogen in $\mathrm{H}_{3} \mathrm{~L}\left(\mathrm{ClO}_{4}\right)_{2} \cdot \mathrm{H}_{2} \mathrm{O}$ were localized in the Fourier difference maps, introduced in the calculation, and freely refined. In $\mathrm{H}_{3} \mathrm{~L}\left(\mathrm{ReO}_{4}\right)_{2}$, the acidic hydrogen atoms were introduced in the calculated position, linked to the pyridine nitrogens as found in the perchlorate salt, while in $\mathrm{HL} \cdot \mathrm{EtOH} \cdot \mathrm{H}_{2} \mathrm{O}$ both water hydrogen atoms were not localized in the Fourier difference map and not introduced in the calculation. The labeling schemes for anion complexes are reported in Figure S2. Selected H-bond contacts are listed in Table S1. CCDC numbers 2253138-2253140.

Table 1. Crystal data and structure refinement for $\mathrm{HL} \cdot \mathrm{EtOH} \cdot \mathrm{H}_{2} \mathrm{O}, \mathrm{H}_{3} \mathrm{~L}\left(\mathrm{ReO}_{4}\right)_{2}$, and $\mathrm{H}_{3} \mathrm{~L}\left(\mathrm{ClO}_{4}\right)_{2} \cdot \mathrm{H}_{2} \mathrm{O}$.

### 2.8. Hirshfeld Surface Analysis

The Hirshfeld surface and the fingerprint plots were calculated using the Crystalexplorer17 software [51].

## 3. Results and Discussion

### 3.1. Ligand Protonation

The acid/base properties of HL were determined in order to know in which pH regions the different protonated forms of the receptor are formed and, thus, to be able to select the appropriate conditions for the synthesis of the anion complexes.

The analysis of the potentiometric titration curves, performed with the program HYPERQUAD [47], showed that HL undergoes one deprotonation in alkaline solutions and three protonations in acidic solutions: the corresponding equilibrium constants are reported in Table 2.

Table 2. Protonation constants determined in $0.1 \mathrm{M} \mathrm{NMe}_{4} \mathrm{Cl}$ aqueous solution at $298.1 \pm 0.1 \mathrm{~K}$. Standard deviations are reported in parentheses.

| Equilibrium | Log $K$ |
| :---: | :---: |
| $\mathrm{~L}^{-}+\mathrm{H}^{+}=\mathrm{HL}$ | $11.88(1)$ |
| $\mathrm{HL}+\mathrm{H}^{+}=\mathrm{H}_{2} \mathrm{~L}^{+}$ | $5.82(3)$ |
| $\mathrm{H}_{2} \mathrm{~L}^{+}+\mathrm{H}^{+}=\mathrm{H}_{3} \mathrm{~L}^{2+}$ | $3.04(3)$ |
| $\mathrm{H}_{3} \mathrm{~L}^{2+}+\mathrm{H}^{+}=\mathrm{H}_{4} \mathrm{~L}^{3+}$ | $2.17(3)$ |

In agreement with the behavior previously observed for other polyamines containing the same pyrimidine and pyridine groups [13,17,52-55], protonation occurring at high pH values $(\log K=11.88$, Table 2$)$ is attributable to the secondary amine group, bound to the pyrimidine ring, which is deprotonated in very alkaline media, while protonation occurring in the lowest pH range $(\log \mathrm{K}=2.17$, Table 2$)$ is expected to involve the pyrimidine nitroso group (Scheme S1). The spectra of HL recorded in the near-UV at different pH values (Figure 2a,b) confirm this attribution of protonation sites. These spectra are characterized by three bands around 230,257 , and 330 nm which can be assigned to the allowed $\pi-\pi^{*}$ transitions between the $\pi$ orbitals of the pyrimidine group and the overlap of the pyridine band at approximately 260 nm . As can be seen in Figure 2c, the pyrimidine bands undergo
important variation with pH in acidic $(\mathrm{pH}<3)$ and alkaline $(\mathrm{pH}>11.5)$ solutions when protonation involves the pyrimidine chromophore while the spectra are almost invariant in the intermediate region. This intermediate region is dominated by the presence of the HL and its monoprotonated $\mathrm{H}_{2} \mathrm{~L}^{+}$species (Figure 2). As the pyridine band at 260 nm is expected to increase upon protonation [56], the invariance of this band suggests that protonation of HL to give $\mathrm{H}_{2} \mathrm{~L}^{+}$occurs on the tertiary amine group (Scheme S1). Further protonation to form $\mathrm{H}_{3} \mathrm{~L}^{2+}$ necessarily involves a pyridine group and, indeed, the 260 nm band increases but the increase is accentuated by the almost concomitant formation of $\mathrm{H}_{4} \mathrm{~L}^{3+}$ in which, as already commented, the pyrimidine chromophore becomes protonated on the nitroso group.

Figure 2. UV spectra of HL in the pH ranges 0.80-7.24 (a) and 7.24-12.58 (b). (c) Absorbances at $257 \mathrm{~nm}(\bullet)$ and $330 \mathrm{~nm}(\square)$ from the above spectra superimposed to the distribution diagram of the species formed by HL as a function of pH . $[\mathrm{HL}]=2 \times 10^{-5} \mathrm{M}$.

As for the location of the two ammonium groups in $\mathrm{H}_{3} \mathrm{~L}^{2+}$, different alternatives should be considered: (i) one proton is located on the tertiary nitrogen atom (as in $\mathrm{H}_{2} \mathrm{~L}^{+}$) and one on a pyridine; (ii) both pyridine groups are protonated; and (iii) protonation involves all three basic centers and there are several species in equilibrium with each other. The first alternative would be favored by the higher basicity of the tertiary amino group but could generate a strong repulsion between the neighboring ammonium groups, while, in the case of the second alternative, this electrostatic repulsion would be reduced since the two pyridines are the protonation sites which can stay at the maximum distance from each other. The third alternative would be a compromise between the first two. The crystal structures of perchlorate salt described below show that $\mathrm{H}_{3} \mathrm{~L}^{2+}$ contains two pyridinium groups, thus corroborating the second alternative (ii) (Scheme S1).

Based on the solution results, we decided to prepare the anion complexes at pH 2.5 in order to have in the solution the maximum abundance of the $\mathrm{H}_{3} \mathrm{~L}^{2+}$ species (Figure 2c). Although at such $\mathrm{pH}, \mathrm{H}_{2} \mathrm{~L}^{+}$and $\mathrm{H}_{4} \mathrm{~L}^{3+}$ are also present in significant amounts, only
the $\mathrm{H}_{3} \mathrm{~L}\left(\mathrm{ReO}_{4}\right)_{2}$ and $\mathrm{H}_{3} \mathrm{~L}\left(\mathrm{ClO}_{4}\right)_{2} \cdot \mathrm{H}_{2} \mathrm{O}$ salts were obtained and in fairly good yields (see Sections 2.3 and 2.4 above).

### 3.2. Crystallographic Study

### 3.2.1. Crystal Structure of $\mathrm{HL} \cdot \mathrm{EtOH} \cdot \mathrm{H}_{2} \mathrm{O}$

The crystal structure of the free ligand (HL), featuring co-crystallized ethanol and water molecules, is dominated by $\pi-\pi$ stacking forces.

The arms of the tripodal ligand assume an overall Y conformation (Figure 3). One of the clefts of the ligand fully closes as one of the pyridine pendants gives face-to-face $\pi-\pi$ stacking interaction with the nitroso-pyrimidine moiety (Figure 3, the dihedral angle between the rings' planes is 15.8 deg , the distance between ring centroids is $3.81 \AA$, and the shortest contact is C2 $\cdots$ C11 3.389(4) $\AA$ ), resulting in a local U fold. Above and below, the same aromatic groups are involved in pyrimidine-pyrimidine (ring centroids distance $3.46 \AA$ ) or pyridine-pyridine (ring centroids distance $3.89 \AA$ ) $\pi$-stacking contacts connecting centrosymmetric molecules which stack upon each other forming columns (Figure 4).

As required by both intrinsic ring polarity and consequent space group symmetry, both pyridine-pyridine and pyrimidine-pyrimidine contacts feature the two neighboring rings in antiparallel disposition. Antiparallel stacks are then connected by $\mathrm{NH}_{2} \cdots \mathrm{Nar}$ H-bonds (N2 $\cdots \mathrm{N}^{\prime} 2.909(5) \AA$ ).

The second pyridine arm is not involved in face-to-face $\pi-\pi$ stacking contacts, but it rather protrudes from, and panels, said stacked columns, being, moreover, involved in hydrogen bonding with solvent molecules. Beyond the N8‥O3' hydrogen bond (2.875(4) A), neighboring hydrogen-bonded stacks interact with each other through further co-crystallized solvent-mediated (O3 $\cdots \mathrm{O} 42.735(4) \AA$ ) H-bonds, namely N5 $\cdots \mathrm{O} 3$ and O4 $\cdots \mathrm{N} 1^{\prime}(2.791(3) \AA$ and 2.963(4) $\AA$, respectively (Figure S3, Table S1).

Figure 3. Asymmetric unit content of the $\mathrm{HL} \cdot \mathrm{EtOH} \cdot \mathrm{H}_{2} \mathrm{O}$ crystal structure with atom labeling.

Figure 4. Repeats of antiparallel stacks of ligands (orange/green) featuring alternate head-to-tail pyridine/pyridine or pyrimidine/pyrimidine $\pi-\pi$ stacking contacts in $\mathrm{HL} \cdot \mathrm{EtOH} \cdot \mathrm{H}_{2} \mathrm{O} . \mathrm{H}$-bonded dimers alternate between inter- and intra-strand. The third arm of each ligand, not involved in strand formation, is shown as a wireframe. Hydrogen atoms and co-crystallized solvent molecules are omitted for clarity. Distances in $\AA$.

### 3.2.2. Crystal Structures of the Anion Cleft Complexes $\mathrm{H}_{3} \mathrm{~L}\left(\mathrm{ReO}_{4}\right)_{2}$ and $\mathrm{H}_{3} \mathrm{~L}\left(\mathrm{ClO}_{4}\right)_{2} \cdot \mathrm{H}_{2} \mathrm{O}$

The two structures can be considered isomorphous, having the same space group and almost the same cell parameters. The diprotonated ligand and the two anions (Figure 5) define very similar structural motifs: the U-shaped conformation seen for the not protonated ligand is now open and the three aromatic rings give two clamps gripping the two anions via anion $-\pi$ interactions. The acidic hydrogens, which have been localized in the $\Delta \mathrm{F}$ map for the perchlorate complex, are linked to both the pyridine nitrogen atoms, as expected from solution studies, and converge towards the nitroso oxygen of an adjacent symmetryrelated ligand molecule (perchlorate complex: N7…O1 2.700(5) $\AA$, N8 $\cdots$ O1 $2.793(6) \AA$; perrhenate complex: N7‥O1 2.67(1) A, N8…O1 2.62(1) A, Table S1, see Figures S4 and S5 for the labeling scheme of both structures).

The pyrimidine-pyridine-pyridine ring sequence gives rise to the following dihedrals: $71.9 / 87.6 \mathrm{deg}$ and $58.2 / 81.7 \mathrm{deg}$ for the perchlorate and the perrhenate salt, respectively (Figure S6). Beyond these little differences, the ligand conformations are virtually identical (RMSD all atoms 0.2013), with their superposition, as shown in Figure 6, allowing us to discuss details of the anion-binding modes. The anion held by the pyridine-pyridine clamp has a very similar coordination mode, its central atom (Cl1 or Re2) being essentially located in the same position with respect to the ligand. These anions are equidistant from the two pyridine rings (Cl1 distance from pyridines centroids 4.089/4.108 $\AA$, Re2 distance from pyridines centroids $4.172 / 3.958 \AA$ ) and give short contacts with the protonated nitrogen
atoms and with the neighboring aromatic carbon (shortest contacts range from $3.007(5) \AA$ to $3.146(6) \AA$ in the perchlorate salt and from $2.90(1) \AA$ to $3.18(1) \AA$ in the perrhenate salt).

Figure 5. Synopsis of the perchlorate (top) and perrhenate (bottom) complexation inside the ligand clefts in the crystal structures of $\mathrm{H}_{3} \mathrm{~L}\left(\mathrm{ClO}_{4}\right)_{2} \cdot \mathrm{H}_{2} \mathrm{O}$ and $\mathrm{H}_{3} \mathrm{~L}\left(\mathrm{ReO}_{4}\right)_{2}$.

The second cleft features two different aromatics, the polysubstituted pyrimidine being the most apt to anion $-\pi$ binding. As a matter of fact, Cl 2 perchlorate is closer to the pyrimidine ring $(\mathrm{O} 24 \cdots \mathrm{~N} 42.977(4) \AA, \mathrm{O} 23 \cdots \mathrm{C} 23.290(6) \AA)$ than to the pyridine ring (O22 $\cdots \mathrm{N} 73.123(6) \AA$ ), as expected (Figure S4). Instead, the Re1 perrhenate anion is almost equally distant from both rings ( $\mathrm{O} 11 \cdots \mathrm{C} 13$ 3.18(1) $\AA, \mathrm{O} 13 \cdots \mathrm{~N} 43.169(9) \AA$, Figure S5). The mutual positions of these anions with respect to the ligand cleft is arguably the major difference between the two crystal structures, the difference being manifest in Figure 6. Such tuning of the ligand-anion interactions seem to stem from two other supramolecular forces at work, hydrogen bonding, and anion-anion contacts among perrhenate species, as shown in Figure 7.

Figure 6. Superposition of the $\mathrm{H}_{3} \mathrm{~L}^{2+}$ cations found in the crystal structures of $\mathrm{H}_{3} \mathrm{~L}\left(\mathrm{ReO}_{4}\right)_{2}$ and $\mathrm{H}_{3} \mathrm{~L}\left(\mathrm{ClO}_{4}\right)_{2} \cdot \mathrm{H}_{2} \mathrm{O}$ and differences in the relative positions of the anions inside the clefts.

Figure 7. Details of further intermolecular contacts determining the exact disposition of anions bound within the pyrimidine-pyridine cleft in the crystal structures of $\mathrm{H}_{3} \mathrm{~L}\left(\mathrm{ClO}_{4}\right)_{2} \cdot \mathrm{H}_{2} \mathrm{O}$ (above) and $\mathrm{H}_{3} \mathrm{~L}\left(\mathrm{ReO}_{4}\right)_{2}$ (below).

For both anions, the N5 nitrogen is involved in the binding. In the perrhenate case, this translates to a direct Re1-O14 $\cdots \mathrm{HN} 5$ hydrogen bond ( $\mathrm{O} \cdots \mathrm{N}$ distance 3.044(8) $\AA$, Table S1). The same interaction in the monohydrate perchlorate complex is mediated by the solvent molecule, which also bridges two symmetry-related anions (H-bond distances: N5...OW1 $2.756(6) \AA, \mathrm{Cl} 2-\mathrm{O} 21 \cdots \mathrm{OW} 12.831(6) \AA$, OW1 $\cdots \mathrm{O} 22-\mathrm{Cl} 2$ 2.885(5) $\AA$, Table S1). Perrhenate
anions are also involved in weak mutual interactions with the establishment of a mutual $\mathrm{O} \cdots \operatorname{Re} / \operatorname{Re} \cdots \mathrm{O}$ contact $\left(\mathrm{O} 14 \cdots \operatorname{Re} 1^{\prime} 3.602(6) \AA\right.$ ), which happens through one of the faces of the $\mathrm{ReO}_{4}{ }^{-}$tetrahedron. Similar contacts have been previously observed and recently dubbed matere bonds [57,58].

### 3.2.3. FT-IR Spectra Analysis

FT-IR spectra recorded on the crystalline samples of $\mathrm{HL} \cdot \mathrm{EtOH} \cdot \mathrm{H}_{2} \mathrm{O}, \mathrm{H}_{3} \mathrm{~L}\left(\mathrm{ClO}_{4}\right)_{2} \cdot \mathrm{H}_{2} \mathrm{O}$, and $\mathrm{H}_{3} \mathrm{~L}\left(\mathrm{ReO}_{4}\right)_{2}$ are shown in Figure S7. If we exclude the signals attributable to ethanol ( $900,1157,1219,1238 \mathrm{~cm}^{-1}$ ), which are present in the spectrum of $\mathrm{HL} \cdot \mathrm{EtOH} \cdot \mathrm{H}_{2} \mathrm{O}$, and some alteration of the relative intensity of the bands, the three spectra are essentially very similar, the main differences consisting in the presence of the typical bands of $\mathrm{ClO}_{4}^{-}$(3361, $1065,613 \mathrm{~cm}^{-1}$ ) and $\mathrm{ReO}_{4}^{-}\left(895 \mathrm{~cm}^{-1}\right)$ [59]. The intense bands at $1065 \mathrm{~cm}^{-1}$ and $895 \mathrm{~cm}^{-1}$ due to the characteristic $\mathrm{Cl}-\mathrm{O}$ and $\mathrm{Re}-\mathrm{O}$ asymmetric stretching vibrations of $\mathrm{ClO}_{4}^{-}$and $\mathrm{ReO}_{4}{ }^{-}$in the spectra of $\mathrm{H}_{3} \mathrm{~L}\left(\mathrm{ClO}_{4}\right)_{2} \cdot \mathrm{H}_{2} \mathrm{O}$ and $\mathrm{H}_{3} \mathrm{~L}\left(\mathrm{ReO}_{4}\right)_{2}$, respectively, are red-shifted as compared to spectra reported for $\mathrm{MClO}_{4}\left(1076-1100 \mathrm{~cm}^{-1}, \mathrm{M}=\mathrm{Li}^{+}, \mathrm{Na}^{+}, \mathrm{NH}_{4}{ }^{+}\right.$[60-62]) and $\mathrm{MReO}_{4}\left(913-928 \mathrm{~cm}^{-1}, \mathrm{M}=\mathrm{Na}^{+}, \mathrm{K}^{+}, \mathrm{NH}_{4}^{+}[63,64]\right)$, manifesting the effect of anion complexation within the protonated ligand clefts.

### 3.2.4. Hirshfeld Surface Analysis

The Hirshfeld surface of the free ligand and corresponding fingerprint plot are reported in Figure 8.

Figure 8. (Top): views of the HL Hirshfeld surface ( $\mathrm{d}_{\text {norm }}$ coloring) in the $\mathrm{HL} \cdot \mathrm{EtOH} \cdot \mathrm{H}_{2} \mathrm{O}$ crystal structure. (Bottom): global fingerprint plot.

The Hirshfeld surface of HL is a rather flat block, delimited on top and bottom sides by intracolumn $\pi-\pi$ stacking interactions and, on its sides, by intercolumn interactions, the most significant of which are the above-mentioned N2 $\cdots \mathrm{N} 7$ hydrogen bonds.

The fingerprint plot shows both typical H-bond tips and a manifest $\pi-\pi$ stacking area (green portion of the graph centered at $\{1.7,1.7\}$ coordinates). These are the same interaction types emerging from overall contact percentages (Table S2), with the further addition of $\mathrm{H} \cdots \mathrm{O}$ contacts due to hydrogen bonding to solvent molecules. The pseudosymmetry of the fingerprint graph is only slightly broken by the presence of the co-crystallized solvent molecules.

The Hirshfeld surface of the diprotonated ligand in the perchlorate and perrhenate complexes and corresponding fingerprint plots are shown in Figures 9 and 10, respectively.

Figure 9. (Top): views of the $\mathrm{H}_{3} \mathrm{~L}^{2+}$ Hirshfeld surface ( $\mathrm{d}_{\text {norm }}$ coloring) in the $\mathrm{H}_{3} \mathrm{~L}\left(\mathrm{ClO}_{4}\right)_{2} \cdot \mathrm{H}_{2} \mathrm{O}$ crystal structure with main contacts highlighted and the full fingerprint plot. (Bottom): focus on the anion binding inside the clefts with detail of the $\mathrm{C} \cdots \mathrm{O}$ contact portion of the fingerprint plot. A shape index coloring scheme is also used to highlight the anion inclusion inside the binding pockets.

Figure 10. (Top): views of the $\mathrm{H}_{3} \mathrm{~L}^{2+}$ Hirshfeld surface ( $\mathrm{d}_{\text {norm }}$ coloring) in the $\mathrm{H}_{3} \mathrm{~L}\left(\mathrm{ReO}_{4}\right)_{2}$ crystal structure with main contacts highlighted and the full fingerprint plot. (Bottom): focus on the anion binding inside the clefts with detail of the $\mathrm{C} \cdots \mathrm{O}$ contact portion of the fingerprint plot. A shape index coloring scheme is also used to highlight the anion inclusion inside the binding pockets.

Main interaction hotspots, as judged from the $d_{\text {norm }}$ parameter, belong to the ligandligand H-bonds, namely among pyridinium sites and NO oxygen.

Anions are found in molecular clefts. The anion $-\pi$ interaction is not as immediately manifest due to the simultaneous presence of H-bond type interactions, which, being both stronger and more directional, are easier to spot both from $d_{\text {norm }}$ hotspots on the Hirshfeld surface and as sharp tips in the fingerprint plots. However, if C $\cdots$ O, i.e., anion $-\pi$ type contacts, are highlighted, the interaction is observed to be significantly represented in the fingerprint plot [22], and to account for a significant portion of the global Hirshfeld surface area ( $5.9 \%$ and $6.3 \%$ for $\mathrm{ClO}_{4}{ }^{-}$and $\mathrm{ReO}_{4}{ }^{-}$, respectively, Tables S 3 and S4). The supramolecular hosting of anionic species is here perhaps better visualized through the shape index coloring, which is effective at showing inward/outward local bending of the Hirshfeld surface itself. As can be observed, anion-binding clefts are among the areas that show the most significant inward bending (red), signaling how the ligand's surface engulfs the anions (Figures 9 and 10 bottom).

Of course, the contribution of these weak forces combines and synergizes with the electrostatic attraction generated between anions and ligands as a consequence of the positive charge introduced by protonation on the pyridine groups, which reverberates throughout the ring as evidenced by the calculated potential electrostatic surfaces (ESP) shown in Figure S8.

## 4. Conclusions

Tripodal ligands are convenient building blocks for easy and fast synthesis of efficient anion receptors. An example is given here by the HL ligand, characterized by a trenlike (tren $=$ tris(2-aminoethyl)amine) structure bearing two pyridine and one pyrimidine terminal functionalities, whose synthesis was accomplished by means of a single reaction from commercial products. The crystal structure of the free ligand shows that the three arms decorated with aromatic groups define molecular clefts where host species can be included. Upon protonation, the ligand opens these clefts as wide as necessary for tight inclusion of large anions such as perchlorate and perrhenate, as shown in the solid state by the crystal structures of $\mathrm{H}_{3} \mathrm{~L}\left(\mathrm{ClO}_{4}\right)_{2} \cdot \mathrm{H}_{2} \mathrm{O}$ and $\mathrm{H}_{3} \mathrm{~L}\left(\mathrm{ReO}_{4}\right)_{2}$. The ligand arms act as clamps gripping the two anions via anion $-\pi$ interactions which are the main forces, in addition to the electrostatic attraction exerted by the ammonium groups that participate in strengthening the host-guest association. Intermolecular hydrogen bonding, $\pi$-stacking, and anion-anion interactions, in the case of perrhenate, contribute to stabilizing the crystal packing.

#### Abstract

Heterotopic ligands containing chemically different binding centers are appealing candidates for obtaining heteronuclear metal complexes. By exploiting this strategy, it is possible to introduce different paramagnetic centers characterized by specific anisotropic magnetic properties that make them distinguishable when weakly magnetically coupled. This molecular approach has great potential to yield multi-spin adducts capable of mimicking logical architectures necessary for quantum information processing (QIP), i.e., quantum logic gates. A possible route for including a single-ion magnetic center within a finite-sized heterometallic compound uses the asymmetric (1-pyridyl)-butane-1,3-dione (pybd) ligand reported in the literature for obtaining $\mathrm{Cr}^{3+}-\mathrm{Cu}^{2+}$ metallocages. To avoid the formation of cages, we adopted the cyclen (1,4,7,10-tetraazacyclododecane) ligand as a "capping" agent for the $\mathrm{Cu}^{2+}$ ions. We report here the structural and magnetic characterization of the unprecedented adduct $\left\{\mathrm{Cr}(\mathrm{pybd})_{3}[\mathrm{Cu}(\text { cyclen })]_{2}\right\}\left(\mathrm{BF}_{4}\right)_{4}$, whose structure is characterized by a central $\mathrm{Cr}^{3+}$ ion in a distorted octahedral coordination environment and two peripheral $\mathrm{Cu}^{2+}$ ions with square-pyramidal coordination geometries. As highlighted by Continuous Wave Electron Paramagnetic Resonance (EPR) spectroscopy and Direct Current (DC) magnetometry measurements, this adduct shows negligible intramolecular magnetic couplings, and it maintains the characteristic EPR signals of $\mathrm{Cr}^{3+}$ and $\mathrm{Cu}^{2+}$ moieties when diluted in frozen solutions.

## 1. Introduction

The qubit, the quantum analog of classical bits, bases its working principles on quantomechanical laws such as the superposition of states. In principle, it is possible to exploit two spin levels of an unpaired electron as the computational basis and encode the information in linear combinations of these states [1]. Magnetic molecules characterized by good spin coherence properties are appealing candidates for improving the quantum logical units of quantum computers $[2,3]$. They can work as qubits when two electronic spin levels are employed to encode the information (e.g., the $m_{S}= \pm 1 / 2$ projections along the quantization axis of an $S=1 / 2$ system) $[4,5]$ or as qudits when more electronic and nuclear spin levels are involved [6,7].

When connected through specific channels (e.g., superconductive planar waveguides [8]), multi-qubit architectures capable of implementing more complex logic operators known as quantum logic gates can be achieved [9]. Likewise, it is possible to "connect" different molecular spins to mime such architectures present in modern quantum processors [10].

Beyond the tailoring of organic ligands and molecules to obtain multi-spin structures [11,12], many other conditions must be fulfilled. For instance, most logical operations and quantum algorithms require that qubits can act as entangled objects. In other words, an interaction between the two spins must be active, and the total state cannot be expressed as a simple product of the individual spin states. Besides this, entangled qubits must be individually addressable so that the selective manipulation of qubits results in the detectable variation of the counterparts quantum states. Magnetic interactions between the spin centers, dipolar or isotropic exchange in nature [11-14], can be exploited to achieve the required entanglement condition [15]. However, the magnetic coupling interaction should be small enough, typically of the order of $10^{-1}-10^{-2} \mathrm{~cm}^{-1}$, to avoid the formation of a giant spin state. Two main strategies can be used to maintain the individual addressability of spins: (i) the introduction of specific ligands and organic scaffolds that guarantee a different relative orientation of the magnetic anisotropy tensors of spin centers [11,16] or (ii) the exploitation of different metal or spin centers within a single architecture, these being characterized by different magnetic anisotropy tensors [17-19].

Heterometallic coordination compounds are of high interest in various fields, spanning from catalysis [20-23] to molecular magnetism [24-28]. Obtaining such structures is not a trivial task, and a tailored design of employed ligands, eventually heterotopic ones [29-31], is often necessary. The use of heterometallic structures has been proposed as a potential strategy to implement quantum logic gates. As reported in [12], the entanglement condition among the different qubits within these architectures can be selectively enabled upon applying specific pulse sequences. In this sense, such a strategy is preferable to the first one since it allows us to mime what commonly happens in quantum circuits, where qubits act as single objects or entangled units upon necessity. However, two critical aspects can be identified for this strategy: (i) the obtainment of heterometallic multi-qubit systems is not trivial, nor are the design and synthetic efforts required [32]; (ii) it is difficult to predict the final quantum and magnetic properties of adducts, where parties can behave differently compared to their isolated forms.

Among the most investigated systems, molecular metallocages represent a significant part of reported systems $[31,33,34]$. Starting from the works of Brechin and coworkers on Cr-based cages built by the (1-pyridyl)-butane-1,3-dione (Hpybd) ligand [30,35-37], we focused on obtaining a heterometallic system by using the same ligand. Such a ligand allows for getting octahedral complexes of $\mathrm{M}^{3+}$ ions thanks to the coordinating nature of the diketonate core. Then, by further exploiting the peripheral pyridyl functions, it is also possible to coordinate up to three additional ions per $\mathrm{M}^{3+}$ unit. In our case, we exploited the ditopic nature of this ligand to obtain a heterometallic complex containing a central $\mathrm{Cr}^{3+}$ ion and $\mathrm{Cu}^{2+}$-based peripheral units. Differently from previous reports [30,35], we exploited the pyridyl units to coordinate a $\mathrm{Cu}^{2+}$ complex, i.e., the $[\mathrm{Cu} \text { (cyclen) }]^{2+}$ (cyclen $=1,4,7,10-$ tetraazacyclododecane). Using the cyclen moiety as a "capping agent" allowed us to get a finite-size complex that avoids forming polymers or cage-like structures.

In this work, we report the structural characterization of the $\left\{\mathrm{Cr}(\mathrm{pybd})_{3}[\mathrm{Cu}(\text { Cyclen })]_{2}\right\}$ $\left(\mathrm{BF}_{4}\right)_{4}$ compound followed by powder X-ray diffraction studies and data analysis. Furthermore, we report the investigation of the static magnetic properties of the adduct performed by standard magnetometry and electron paramagnetic resonance (EPR) spectroscopy.

## 2. Materials and Methods

2.1. Synthesis

### 2.1.1. General Remarks

All the reagents and solvents were of reagent grade and employed without further purification. Compounds Hpybd and $\left[\mathrm{Cr}(\mathrm{pybd})_{3}\right]$ were synthesized according to the literature [30]. More details about the synthesis of all the other compounds are reported in Section S1 of Supplementary Information (SI). A general reaction pathway is reported in Scheme 1 for clarity.

Scheme 1. Synthetic schemes showing the general strategies employed for the obtaining of reported compounds. (a) Synthesis of Hpybd and $\left[\mathrm{Cr}(\mathrm{pybd})_{3}\right]$. (b) Synthesis of $\left[\mathrm{Cu}(\right.$ cyclen $\left.) \mathrm{BF}_{4}\right]\left(\mathrm{BF}_{4}\right)$. (c) Synthesis of the macromolecular adduct $\left\{\mathrm{Cr}(\mathrm{pybd})_{3}[\mathrm{Cu}(\text { cyclen })]_{2}\right\}\left(\mathrm{BF}_{4}\right)_{4}$.

### 2.1.2. Synthesis of $\left\{\mathrm{Cr}(\text { pybd })_{3}[\mathrm{Cu}(\text { cyclen })]_{2}\right\}\left(\mathrm{BF}_{4}\right)_{4}$

In a 50 mL two-neck flask equipped with a condenser, $\left[\mathrm{Cu}\right.$ (cyclen) $\left.\mathrm{BF}_{4}\right] \mathrm{BF}_{4}(235 \mathrm{mg}$, 0.6 mmol ) was dissolved in 15 mL of MeOH and heated to reflux under magnetic stirring. A solution of $\left[\mathrm{Cr}(\mathrm{pybd})_{3}\right](100 \mathrm{mg}, 0.2 \mathrm{mmol})$ in $\mathrm{CHCl}_{3}(5 \mathrm{~mL})$ was added dropwise to the reaction mixture, and the solution refluxed for 1 h . Then, the solution was cooled to room temperature, filtered, and evaporated slowly. After three days, a crystalline product ( $218 \mathrm{mg}, 85 \%$ ) was collected by filtration and washed with $\mathrm{CHCl}_{3}(5 \mathrm{~mL} \times 2)$ and $\mathrm{Et}_{2} \mathrm{O}$ ( $5 \mathrm{~mL} \times 2$ ). The grounded powder was employed for structural determination (see below). Elemental analysis (calc. for $\mathrm{CrCu}_{2} \mathrm{C}_{43} \mathrm{H}_{64} \mathrm{~N}_{11} \mathrm{O}_{6} \mathrm{~B}_{4} \mathrm{~F}_{16}$ ): C, 38.45 (38.05); H, 4.37 (4.75); $\mathrm{N} ; 11.29$ (11.35). UV/Vis ( $\left.\lambda_{\max }, \mathrm{nm}\right)$ : 279, 368, $587\left(\varepsilon=43 \mathrm{M}^{-1} \mathrm{~cm}^{-1}\right)$; see also Figure S1. FT-IR ( $\mathrm{v}, \mathrm{cm}^{-1}$ ): 3325(w), 3306(s), 3129(vw), 2941(w), 2895(w), 1585(m), 1545(w), 1515(s), 1495(vw), 1429(m), 1394(s), 1322(vw), 1291(m), 1250(vw), 1217(w), 1081 (vs, b), 1057(vs, b) 974(m, b), 955(vw, b), 867(w), 849(w), 810(vw), 775(m), 701(s), 619(s) (Figure S2 of SI).

### 2.2. UV-Vis Spectroscopy

UV-Vis spectra were recorded on a Jasco V-670 double-beam spectrophotometer by using quartz cuvettes of 1 cm length. All experiments were performed on 0.25 M MeOH solutions of employed compounds. All experimental spectra are reported in Figures S1 and S3 of SI.

### 2.3. X-ray Structural Characterization

Single-crystal X-ray diffraction was employed to obtain the unit cell parameters. A single crystal was analyzed at 100 K using $\mathrm{Cu}-\mathrm{K} \alpha$ radiation ( $\lambda=1.54184 \AA$ ) on a Bruker Apex-II diffractometer equipped with pixel array detector PhotonII, controlled using APEX2 software [38].

Powder X-ray Diffraction (PXRD) was used for structure determination using unit cell parameters extracted from single crystal data. High-quality PXRD data were recorded in a 0.3 mm glass capillary at room temperature by using a Bruker New D8 Da Vinci diffractometer $(\mathrm{Cu}-\mathrm{K} \alpha 1$ radiation $=1.54056 \AA$, $40 \mathrm{kV} \times 40 \mathrm{~mA})$ equipped with a Bruker LYNXEYE-XE detector, scanning range $2 \theta=3-70^{\circ}, 0.02^{\circ}$ increments of $2 \theta$, and a counting time of 576 total time/step. Space group determination with EXPO2014 [39] resulted in space group $\mathrm{P}-1$ with $\mathrm{Z}=2$. We then solved the structure by stimulated annealing using the EXPO2014 suite. Each annealing trial works on three runs, using a cooling rate $\left(T_{n} / T_{n-1}\right)$ of 0.95 . All the torsion angles were allowed to rotate freely during the refinement process while bond distances and angles were kept fixed. The best solution was chosen for Rietveld refinement, which was performed with the software TOPASv6 [40]. Background and peak shape were fitted using a shifted Chebyshev function with eight coefficients and a Pseudo-Voigt function, respectively. All atoms were isotropically refined with a typical thermal parameter depending on the element. All the hydrogen atoms were fixed in calculated positions. Crystal data and refinement parameters are reported in Table 1. The simulated pattern was obtained by using the software Mercury CSD 2022.2.0 (copyright CCDC, https:/ /www.ccdc.cam.ac.uk/solutions/software/mercury, accessed: 26 May 2023) [41] by employing an FWHM value of 0.1 and an increment step size of $0.025^{\circ}$. Complete crystallographic data for the solved structures have been deposited in the Cambridge Crystallographic Data Centre with CCDC number 2260168.

Table 1. Crystallographic data and refinement parameters.

| Molecular Formula | $\mathrm{C}_{42} \mathrm{CrCu}_{2} \mathbf{N}_{\mathbf{1 2}} \mathrm{O}_{6}, \mathbf{4}\left(\mathbf{B F}_{4}\right)$ |

### 2.4. DC Magnetometry

Direct current (DC) magnetic measurements were performed in the temperature range $2-300 \mathrm{~K}(\mathrm{~B}=0.1 \mathrm{~T})$ or in the field range $0-5 \mathrm{~T}(\mathrm{~T}=2 \mathrm{~K}, 4 \mathrm{~K}, 8 \mathrm{~K})$ using a Quantum Design Magnetic Properties Measuring System (QD-MPMS) equipped with a Superconductive Quantum Interference Device (SQUID). Magnetization data were corrected for the diamagnetic contributions of sample holders (previously measured using the same conditions) and of the sample itself, as deduced by using Pascal's constant tables [42].

### 2.5. Electron Paramagnetic Resonance (EPR) Spectroscopy

CW X-band EPR spectra of all samples were recorded on a Bruker Elexsys E500 spectrometer equipped with an SHQ cavity ( $v=9.43 \mathrm{GHz}$ ). Low-temperature measurements were obtained using an Oxford Instruments ESR900 continuous-flow helium cryostat. All measured samples were 0.5 mM solutions of employed compounds in $\mathrm{EtOH} / \mathrm{MeOH} 4: 1$. The solutions were introduced within a standard X-band quartz tube and rapidly frozen in a liquid nitrogen bath to obtain dispersions in glassy matrixes.

## 3. Results and Discussion

### 3.1. Synthesis

The molecular complex $\left[\mathrm{Cr}(\mathrm{pybd})_{3}\right]$ was synthesized following the strategy by Brechin et al. [30,35-37]. The reaction of $\mathrm{CrCl}_{3} \cdot 6 \mathrm{H}_{2} \mathrm{O}$ with the Hpybd ligand was performed in water by using urea as the base for deprotonating the employed diketonate. Such a strategy is commonly used to avoid the formation of chromium oxides and hydroxides during the reaction since ammonia slowly develops by urea decomposition at $90^{\circ} \mathrm{C}$ [43]. After purification, the $\left[\mathrm{Cr}(\mathrm{pybd})_{3}\right]$ complex was reacted with three equivalents of the $\mathrm{Cu}^{2+}$ precursor: $\left[\mathrm{Cu}\right.$ (cyclen) $\left.\mathrm{BF}_{4}\right] \mathrm{BF}_{4}$, in a $\mathrm{MeOH} / \mathrm{CHCl}_{3} 6: 1$ solution. This procedure was used with the intent to introduce three Cu units per Cr center, as done in ref. [30], and to obtain the tetramer $\left\{\mathrm{CrCu}_{3}\right\}$. The reaction can be followed by observing the color changing from royal blue to greenish/blue. On cooling, dark crystals formed from the solution, and larger amounts of the product were obtained by slow evaporation of the reaction mixture. Notwithstanding our predictions and efforts to obtain a tetramer, it was only possible to get the trimeric specie $\left\{\mathrm{Cr}(\mathrm{pybd})_{3}[\mathrm{Cu} \text { (cyclen) }]_{2}\right\}\left(\mathrm{BF}_{4}\right)_{4}$ (see below). Interestingly, the obtained compound does not respect the expected $\mathrm{Cr} / \mathrm{Cu} 1: 3$ stoichiometry even though a large excess of $\mathrm{Cu}^{2+}$ precursor is employed. This behavior could be imputed to the steric hindrance introduced by adding $[\mathrm{Cu}(\mathrm{cyclen})]^{2+}$ to the pyridyl units. Furthermore, it was only possible to obtain $\left\{\mathrm{Cr}(\mathrm{pybd})_{3}[\mathrm{Cu}(\text { cyclen })]_{2}\right\}\left(\mathrm{BF}_{4}\right)_{4}$ by slow evaporation of the reaction mixture. Any other attempt to recrystallize it from solutions of different organic solvents and their mixtures (e.g., $\mathrm{MeOH}, \mathrm{CHCl}_{3}, \mathrm{DMSO}$, and DMF) led to the separation of individual $\mathrm{Cr}^{3+}$ and $\mathrm{Cu}^{2+}$ precursors.

### 3.2. Structural Characterization

As mentioned above, $\left\{\mathrm{Cr}(\mathrm{pybd})_{3}[\mathrm{Cu}(\text { cyclen })]_{2}\right\}\left(\mathrm{BF}_{4}\right)_{4}$ (Figure 1 ) crystallizes from the reaction mixture upon cooling and subsequent evaporation of MeOH . Nevertheless, the plate-shaped crystals tend to pile along the $c$ crystallographic axis. For this reason, cutting a single crystal suitable for X-ray structural determination was not possible. Hence, we employed the single-crystal diffraction tool to firstly estimate the cell parameters that were successively used for the structural refinement model employed on PXRD data (see Section 2). We report the comparison between the experimental and simulated PXRD patterns in Figure 2 as proof of the quality of the employed model. The plot evidences a remarkable agreement between experiment and simulation, both in terms of peak positions and relative intensities.

Figure 1. View of the molecular structure of $\left\{\mathrm{Cr}(\mathrm{pybd})_{3}[\mathrm{Cu}(\text { cyclen })]_{2}\right\}\left(\mathrm{BF}_{4}\right)_{4}$. Hydrogen atoms are omitted for clarity. Color code: $\mathrm{Cr}=$ green; $\mathrm{Cu}=$ copper; $\mathrm{F}=$ yellow/green; $\mathrm{O}=$ red; $\mathrm{N}=$ blue; $C=$ grey; $B=$ pink.

Figure 2. Comparison between experimental and simulated PXRD patterns obtained for microcrystalline $\left.\left\{\left[\mathrm{Cr}(\text { pybd })_{3}\right][\mathrm{Cu} \text { (cyclen })\right]_{2}\right\}\left(\mathrm{BF}_{4}\right)_{4}$.
$\left\{\mathrm{Cr}(\text { pybd })_{3}[\mathrm{Cu} \text { (cyclen) }]_{2}\right\}\left(\mathrm{BF}_{4}\right)_{4}$ crystallizes in the $\mathrm{P}-1$ space group (no. 2) with two $\left\{\mathrm{Cr}(\mathrm{pybd})_{3}[\mathrm{Cu}(\text { cyclen })]_{2}\right\}^{4+}$ cationic species and eight $\mathrm{BF}_{4}{ }^{-}$counterions per unit-cell. The asymmetric unit is represented by the $\left\{\mathrm{Cr}(\text { pybd })_{3}[\mathrm{Cu}(\text { cyclen })]_{2}\right\}\left(\mathrm{BF}_{4}\right)_{4}$ unit reported in Figure 1 (unit cell content shown in Figure S3 of SI). The crystal structure also presents solvent-accessible pores, occupying $5 \%$ of the unit cell volume with a volume of about $165 \AA^{3}$ (Figure S4 of SI). The porous structure propagates along the $a$-axis direction.

In the asymmetric unit, the $\mathrm{Cr}^{3+}$ ion preserves the fac isomerism typical of $\left[\mathrm{Cr}(\mathrm{pydb})_{3}\right][30]$ and presents a distorted octahedral coordination geometry having mean $\mathrm{Cr}-\mathrm{O}$ distances of $1.96 \AA$ on the equatorial plane and $\mathrm{Cr}-\mathrm{O} 5$ and $\mathrm{Cr}-\mathrm{O} 6$ distances of $1.93 \AA$ and $1.97 \AA$ along the axial direction (see Figure S5a of SI). Furthermore, all the $\mathrm{O} 2-\mathrm{Cr}-\mathrm{O} 4, \mathrm{O} 1-\mathrm{Cr}-\mathrm{O} 3$, and $\mathrm{O} 5-\mathrm{Cr}-\mathrm{O} 6$ angles are smaller than $180^{\circ}$, being of about $176.0^{\circ}, 177.0^{\circ}$, and $179.0^{\circ}$, respectively (see Figure S5b of SI). Such a distorted octahedral geometry differs from the regular one reported for the $\left[\mathrm{Cr}(\mathrm{pydb})_{3}\right]$ precursor, although it has been observed for $\left[\mathrm{Cr}(\text { pydb })_{3}\right]$-based supramolecular cages $[30,35,36]$. In analogy to the $\mathrm{Cr}^{3+}$ ion, the two $\mathrm{Cu}^{2+}$ moieties present slightly distorted square-pyramidal geometry due to minor differences in the $\mathrm{Cu}-\mathrm{N}_{\text {cyclen }}$ bond lengths (see Figure S 6 of SI ). In this case, the mean $\mathrm{Cu}-\mathrm{N}_{\text {cyclen }}$ distance is $2.03 \AA$ for both cyclen-based units, while the $\mathrm{Cu}-$ Npy distances are $2.15 \AA$ and $2.17 \AA$ for $\mathrm{Cu} 1-\mathrm{N} 5$ and Cu2-N10, respectively. These distances align with other squarepyramidal N -based copper complexes [44]. The mean $\mathrm{Cr}-\mathrm{Cu}$ intramolecular distance is $8.9 \AA$. The smallest $\mathrm{Cu} \cdots \mathrm{Cu}$ intermolecular distance of $7.3 \AA$ is measured between molecules in adjacent cells moving along the $b$-axis. The smallest intermolecular $\mathrm{Cr} \cdots \mathrm{Cr}$ distance is $7.36 \AA$, and it is measured between molecules in adjacent cells along the $c$ axis. The structure presents four $\mathrm{BF}_{4}{ }^{-}$per molecular unit, three of them presenting short-contact interactions with the acidic $\mathrm{N}-\mathrm{H}$ moieties of the two $[\mathrm{Cu}(\text { cyclen })]^{2+}$ units per molecule. At the same time, the fourth is stabilized within the framework by similar interactions set with the cyclen unit of another molecule.

### 3.3. UV-Vis Spectroscopy Characterization

To check for the stability of the $\left\{\left[\mathrm{Cr}(\mathrm{pybd})_{3}\right][\mathrm{Cu}(\text { cyclen })]_{2}\right\}^{4+}$ adduct when in solution and confirm the coordination geometry of metal sites, we performed a UV-Vis spectroscopic investigation on $2.5 \times 10^{-3} \mathrm{M}$ solutions of $[\mathrm{Cu}(\text { cyclen })]^{2+}$ and $\left\{\left[\mathrm{Cr}(\text { pybd })_{3}\right][\mathrm{Cu} \text { (cyclen) }]_{2}\right\}^{4+}$ in MeOH and compared their experimental spectra. To do that, we focused on the spectral region between 400 and 850 nm , where electronic transitions attributed to the copper(II) center are usually observed [44-47]. The graph in Figure 3 shows that the two complexes present an absorption band centered at about 600 nm . In particular, we observed
absorption maxima at $587 \mathrm{~nm}\left(\varepsilon=43 \mathrm{M}^{-1} \mathrm{~cm}^{-1}\right)$ and $601 \mathrm{~nm}\left(\varepsilon=35 \mathrm{M}^{-1} \mathrm{~cm}^{-1}\right)$ for $\left\{\left[\mathrm{Cr}(\text { pybd })_{3}\right][\mathrm{Cu} \text { (cyclen) }]_{2}\right\}^{4+}$ and $[\mathrm{Cu} \text { (cyclen) }]^{2+}$, respectively. This spectral feature is imputed to a $d-d$ transition of the copper center, and the observed energy is characteristic of pentacoordinate complexes having a square-pyramidal coordination geometry [44]. We further compared these UV-Vis spectra with an additional one obtained on a $2.5 \times 10^{-3} \mathrm{M}$ solution of $[\mathrm{Cu} \text { (cyclen) }]^{2+}$ in MeOH added in 100 equivalents of pyridine. This third spectrum shows a red shift of the absorption maximum to $\lambda=617 \mathrm{~nm}\left(\varepsilon=35 \mathrm{M}^{-1} \mathrm{~cm}^{-1}\right)$, which is expected for stronger interactions with an axial ligand on the fifth position [48]. By comparing this spectrum with that obtained on $\left\{\left[\mathrm{Cr}(\mathrm{pybd})_{3}\right][\mathrm{Cu}(\text { cyclen })]_{2}\right\}^{4+}$, we can state that the coordination of the $\mathrm{Cu}^{2+}$ ion by the pyridyl unit of pybd ligand leads to a smaller crystal field interaction with respect to pure pyridine. This can be correlated to a weaker interaction with the unpaired doublet of the N donor atom, whose delocalization on the conjugated $\beta$-diketonate scaffold could be further affected by the electron-withdrawing effect of the coordinated $\mathrm{Cr}^{3+}$ ion.

Figure 3. UV-Vis absorption spectra collected on $2.5 \times 10^{-3} \mathrm{M} \mathrm{MeOH}$ solutions of $[\mathrm{Cu} \text { (cyclen) }]^{2+}$, $[\mathrm{Cu}(\text { cyclen })]^{2+}+100$ eq of pyridine (py), and $\left\{\mathrm{Cr}(\text { pybd })_{3}[\mathrm{Cu}(\text { cyclen })]_{2}\right\}^{4+}$.

### 3.4. Magnetism and EPR Spectroscopy

X-band ( $v \approx 9.4 \mathrm{GHz}$ ) continuous wave EPR measurements were performed to characterize and compare the magnetic anisotropy properties of the presented systems. To do that, we measured frozen solution of $\left[\mathrm{Cr}(\mathrm{pybd})_{3}\right],[\mathrm{Cu}(\text { cyclen })]^{2+}$, and $\left\{\mathrm{Cr}(\text { pybd })_{3}[\mathrm{Cu}(\text { cyclen })]_{2}\right\}^{4+}$ in $\mathrm{EtOH} / \mathrm{MeOH}$ 4:1 (see Section 2). The experimental spectra are reported as blue lines in Figure 4a-c.

The $\left[\mathrm{Cr}(\mathrm{pybd})_{3}\right]$ complex shows the characteristic EPR spectrum of an octahedrally coordinated $\mathrm{Cr}^{3+}$ ion (Figure 4a). The observed spectral features are attributed to spin transitions within the quartet basis state $(S=3 / 2)$ further split in two Kramers' doublets ( $m_{S}= \pm 1 / 2 ; m_{S}= \pm 3 / 2$ ) by the zero-field splitting (ZFS) interaction, which is characterized by axial $(D)$ and rhombic $(E)$ terms following the spin Hamiltonian (SH) in Equation (1).

$$
\begin{equation*}
\hat{H}_{S}^{C r}=-\mu_{B} \hat{S} \cdot g \cdot \vec{B}+D \hat{S}_{z}^{2}+E\left(\hat{S}_{x}^{2}-\hat{S}_{y}^{2}\right) \tag{1}
\end{equation*}
$$

The spectrum can be well simulated [49] with the SH parameters extracted from ref. [30] and reported in Table 1. The chromium complex is characterized by an easy-plane anisotropy $\left(D=+0.55 \mathrm{~cm}^{-1}\right)$ leading to $m_{S}= \pm 1 / 2$ ground doublet. The E/D ratio of 0.045 confirms that the system has a weak rhombic distortion. Such values are in line with what has been reported in the literature for other Cr-acetylacetonate complexes, for which $D$ values of about $0.6 \mathrm{~cm}^{-1}$ have been observed [50,51].

Figure 4. (a) Experimental and simulated X-band EPR spectra of $\left[\mathrm{Cr}(\mathrm{pybd})_{3}\right] 0.5 \mathrm{mM}$ in EtOH/MeOH 4:1; (b) Experimental and simulated X-band EPR spectra of $[\mathrm{Cu} \text { (cyclen) }]^{2+} 0.5 \mathrm{mM}$ in EtOH/MeOH 4:1; (c) Experimental and simulated X-band EPR spectra of $\left\{\mathrm{Cr}(\text { pybd })_{3}[\mathrm{Cu}(\text { cyclen })]_{2}\right\}^{4+} 0.5 \mathrm{mM}$ in EtOH/MeOH 4:1.

The $[\mathrm{Cu} \text { (cyclen) }]^{2+}$ compound showed the EPR spectrum in Figure 4b, which is closely in line with that expected for an $S=1 / 2$ system characterized by an anisotropic axial $g$ tensor with an axial hyperfine coupling interaction $(A)$ between the spin and the copper nucleus $(I=3 / 2)$. A quantitative estimation of the magnetic anisotropy followed from the simulation of the experimental spectrum with the SH reported in Equation (2).

$$
\begin{equation*}
\hat{H}_{S}^{C u}=-\mu_{B} \cdot \hat{S} \cdot \boldsymbol{g} \cdot \vec{B}+\hat{I} \cdot \boldsymbol{A} \cdot \hat{S} \tag{2}
\end{equation*}
$$

The values obtained for the components of $g$ and $A$ tensors (Table 2), for which $g_{1 ।}>g_{\perp}$ and $A_{\mid ।}>A_{\perp}$ (with $z=\|$ and $x=y=\perp$ ), are representative of a pentacoordinate $\mathrm{Cu}^{2+}$ complex $[47,48]$ and confirm the experimental evidence given by the UV-Vis analysis (see above).

Table 2. List of best-simulation parameters extracted for X-band spectra of 0.5 mM frozen solutions in $\mathrm{EtOH} / \mathrm{MeOH} 4: 1$. In the case of the $\mathrm{Cr}-\mathrm{Cu}$ adduct, we did not consider the relative orientation of magnetic reference frameworks of each site.

$\mathrm{a}=$ set of parameters extracted for the $\mathrm{Cr}^{3+}$ ion; $\mathrm{b}=$ set of parameters extracted for the two equivalent $\mathrm{Cu}^{2+}$ sites.
The X-band characterization of $\left\{\mathrm{Cr}(\text { pybd })_{3}[\mathrm{Cu}(\text { cyclen })]_{2}\right\}^{4+}$ was performed at 40 K to avoid saturation of the $\mathrm{Cu}^{2+}$ signal and simultaneously detect that of the $\mathrm{Cr}^{3+}$ ion. The obtained spectrum (Figure 4c) slightly differs from the trivial sum of those of the two precursors. On the one hand, the low-field region between 100 mT and 25 mT , i.e., the most indicative one for the $\mathrm{Cr}^{3+}$ ion signal, largely differs from that of isolated $\left[\mathrm{Cr}(\mathrm{pybd})_{3}\right]$. On the other hand, the $\mathrm{Cu}^{2+}$ signal falling within the $250-400 \mathrm{mT}$ region seems not to be
affected by the presence of the $\mathrm{Cr}^{3+}$ ion. Based on this observation, we can say that there is no evidence of a clear isotropic exchange coupling interaction among the Cr and Cu sites. It follows that the unique modification of the chromium signal should be correlated to the variation of the SH parameters of the $\mathrm{Cr}^{3+}$ ion upon copper coordination of two pyridine rings of the pybd ligand, while those of $\mathrm{Cu}^{2+}$ remain unaltered. To validate such an assumption, we simulated the spectra by fixing the SH parameters of $\mathrm{Cu}^{2+}$ moieties and varying the $D$ and $E$ components of chromium using a SH given by the sum of those reported in Equations (1) and (2). The best simulation reported in Figure 4c was obtained by reducing both the $D$ and $E$ values to $0.21 \mathrm{~cm}^{-1}$ and $0.02 \mathrm{~cm}^{-1}$, respectively.

Consequently, the $E / D$ ratio of the adduct increased to 0.095 , highlighting a larger rhombicity of the system. This feature can be correlated to the distortion of the $\mathrm{Cr}^{3+}$ coordination sphere observed in the case of $\left\{\mathrm{Cr}(\text { pybd })_{3}[\mathrm{Cu} \text { (cyclen) }]_{2}\right\}^{4+}$ (see Structural Characterization section), which led to an increased rhombicity. It must be noted that, in our model, dipolar interactions among spins were not introduced directly, but they were included as contributions to the isotropic and anisotropic line-broadening. These interactions could be better highlighted and investigated by adopting advanced pulsed EPR experiments such as DEER (Double Electron-Electron Resonance) [52].

To further exclude that the lack of magnetic exchange interaction is not a consequence of structural changes occurring in the frozen solution, we measured crystalline powders of $\left\{\mathrm{Cr}(\text { pybd })_{3}[\mathrm{Cu}(\text { cyclen })]_{2}\right\}\left(\mathrm{BF}_{4}\right)_{4}$. However, the EPR spectrum collected on the solid sample is significantly broadened because of intermolecular interactions (Figure S7 of SI), and it cannot pursue our scope. For this reason, we employed DC magnetometry (see Section 2) to get more insights into the magnetic interactions characteristic of the compound. The magnetic susceptibility ( $\chi$ ) data are reported in Figure 5 a as $\chi T$ product vs. T. Above 25 K , the $\chi T$ value reaches a plateau around $2.62 \mathrm{~cm}^{3} \mathrm{~mol}^{-1} \mathrm{~K}$, which is the sum of the Curie's constants expected for the three paramagnetic centers characterized by the ZFS and $\mathbf{g}$ tensors anisotropies determined by our EPR experiments. Below this temperature, the $\chi T$ value drops abruptly to $2.4 \mathrm{~cm}^{3} \mathrm{~mol}^{-1} \mathrm{~K}$. This behavior can be correlated to two distinct factors, i.e., (i) a contribution linked to the ZFS of $\mathrm{Cr}^{3+}$ ion and (ii) a contribution due to intra- or intermolecular coupling interactions within the crystal lattice. In order to estimate the magnitude of such interactions, we performed a simultaneous fit of $\chi T$ vs. $T$ and $M$ vs. $B$ (Figure 5a,b) curves with the software PHI [53]. We used the set of SH parameters extracted from X-band measurements and kept them fixed, while the mean-field intermolecular interactions parameter $(z J)$ was used as the fitting parameter. The employed model provides a best-fit $z J$ value of $1.92(1) \cdot 10^{-2} \mathrm{~cm}^{-1}$. We repeated the same fitting procedure by replacing the mean-field interaction with an equivalent isotropic exchange coupling interaction $\left(H_{\mathrm{ex}}=-J_{\mathrm{Cr}-\mathrm{Cu}}\left(\hat{S}_{\mathrm{Cu} 1} \cdot \hat{S}_{\mathrm{Cr}}+\hat{S}_{\mathrm{Cu} 2} \cdot \hat{S}_{\mathrm{Cr}}\right)\right)$ between the two $\mathrm{Cu}^{2+}$ ions and the central $\mathrm{Cr}^{3+}$ and fitting the coupling constant $J_{\mathrm{Cr}-\mathrm{Cu}}$. The best $J_{\mathrm{Cr}-\mathrm{Cu}}=-5.71(1) \cdot 10^{-2} \mathrm{~cm}^{-1}$ is of the same order of magnitude as the mean-field constant $z J_{s}$ and the fitted curve (red line in Figure 5) poorly reproduces the experimental $\chi T$ points between 2 and 5 K .

This latter analysis, together with our EPR results reported for the diluted phase, suggests that, even if present, exchange coupling interactions are not detectable in the limit of the experimental conditions employed.

Figure 5. (a) $\chi T$ vs. $T$ plot obtained for $\left\{\left[\mathrm{Cr}(\mathrm{pybd})_{3}\right][\mathrm{Cu}(\mathrm{cyclen})]_{2}\right\}\left(\mathrm{BF}_{4}\right)_{4}$ at $B=0.1 \mathrm{~T}$. An asterisk is placed in correspondence of a signal anomaly due to oxygen impurity within the measurement chamber; (b) $M$ vs. $B T^{-1}$ plot obtained for $\left\{\left[\mathrm{Cr}(\mathrm{pybd})_{3}\right][\mathrm{Cu}(\text { cyclen })]_{2}\right\}\left(\mathrm{BF}_{4}\right)_{4}$ at $T=2,4$, and 8 K . Solid lines within the plot correspond to the fitting outcomes.

## 4. Conclusions

In this work, we reported the synthesis of the new molecular cluster $\left\{\mathrm{Cr}(\mathrm{pybd})_{3}[\mathrm{Cu}-\right.$ (cyclen) $\left.]_{2}\right\}\left(\mathrm{BF}_{4}\right)_{4}$ by exploiting the heterotopic properties of the pybd ${ }^{-}$ligand and using cyclen rings as capping agents to avoid the formation of molecular cages. The crystallographic structure has been resolved thanks to a combined approach involving singlecrystal X-ray measurements and powder X-ray diffraction suites. Congruently to our elemental analysis results, the crystallographic characterization unveiled the structural peculiarity of the cluster, which is characterized by the presence of just two coordinated $[\mathrm{Cu}($ cyclen $)] 2+$ moieties over the three potential pyridyl units of the $\left[\mathrm{Cr}(\mathrm{pybd})_{3}\right]$ core. Our X-band CW-EPR measurements on diluted frozen solutions highlighted the variation of the magnetic anisotropy properties of the $\mathrm{Cr}^{3+}$ center in $\left\{\mathrm{Cr}(\mathrm{pybd})_{3}[\mathrm{Cu} \text { (cyclen) }]_{2}\right\}\left(\mathrm{BF}_{4}\right)_{4}$ with respect to the monomeric $\left[\mathrm{Cr}(\mathrm{pybd})_{3}\right]$ unit. The increased rhombic distortion in $\left\{\mathrm{Cr}(\text { pybd })_{3}[\mathrm{Cu}(\text { cyclen })]_{2}\right\}\left(\mathrm{BF}_{4}\right)_{4}$, highlighted by an $E / D$ ratio of $9.5 \cdot 10^{-2}$, can be justified on the basis of crystallographic results, which pinpoints the more significant distortion of the $\mathrm{Cr}^{3+}$ coordination geometry in the trimer compared to the monomer. Furthermore, both EPR and magnetometry measurements highlighted a small coupling interaction between the central spin and the peripheral units, primarily relying on a dipolar coupling interaction between paramagnetic centers. This result is in contrast with what has been observed for $\mathrm{Cu}-\mathrm{Cr}$ macromolecular cages obtained with the same $\left[\mathrm{Cr}(\mathrm{pybd})_{3}\right]$ building block, for which a ferromagnetic coupling interaction of about $10^{-1} \mathrm{~cm}^{-1}$ has been reported [30,35]. However, while the $\mathrm{Cu}^{2+}$ ions included within cages are coordinated on equatorial positions by pyridyl units of the pybd ${ }^{-}$ligand, the same units point toward the axial position of the pentacoordinate $[\mathrm{Cu}(\text { cyclen })]^{2+}$ units present in our cluster. In this respect, we could have expected a lower super-exchange interaction between the $\mathrm{Cr}^{3+}$ and $\mathrm{Cu}^{2+}$ ions in our cluster than in that of ref. [30] since here, the pyridyl unit points towards the doubly occupied $d_{z^{2}}$ of the copper ion, rather than the singly occupied $d_{x^{2}-y^{2}}$. Unfortunately, the change in the orbital involved in the interaction reduces the interaction to a value smaller than the dipolar ones that is not detectable within the employed experimental conditions.

#### Abstract

An unusual heterobimetallic volatile compound $\left[\mathrm{Pb}_{2} \mathrm{Co}_{5}\left(\mathrm{acac}_{14}\right)_{14}\right]$ was synthesized by the gas phase/solid-state technique. The preparation can be readily scaled up using the solution approach. X-ray powder diffraction, ICP-OES analysis, and DART mass spectrometry were engaged to confirm the composition and purity of heterobimetallic complex. The composition is unique among the large family of lead(tin): transition metal $=2: 1,1: 1$, and $1: 2 \beta$-diketonates compounds that are mostly represented by coordination polymers. The molecular structure of the complex was elucidated by synchrotron single crystal $X$-ray diffraction to reveal the unique heptanuclear moiety $\left\{\mathrm{Co}(\mathrm{acac})_{2}\left[\mathrm{~Pb}(\mathrm{acac})_{2}-\mathrm{Co}(\mathrm{acac})_{2}-\mathrm{Co}(\mathrm{acac})_{2}\right]_{2}\right\}$ built upon bridging interactions of acetylacetonate oxygens to neighboring metal centers that bring their coordination numbers to six. The appearance of unique heptanuclear assembly can be attributed to the fact that the $\left[\mathrm{Co}\left(\mathrm{acac}_{2}\right]\right.$ units feature both cisand trans-bis-bridging modes, making the polynuclear moiety rather flexible. This type of octahedral coordination is relatively unique among known lead(tiin)-3d transition metal $\beta$-diketonates. Due to the high-volatility, $\left[\mathrm{Pb}_{2} \mathrm{Co}_{5}(\mathrm{acac})_{14}\right]$ can be potentially applied as a MOCVD precursor for the low-temperature preparation of lead-containing functional materials.

Keywords: single crystal; lead complexes; cobalt complexes; heterometallic structures; heptanuclear molecule

## 1. Introduction

A number of divalent lead-transition metal heterobimetallic compounds $\mathrm{Pb}_{x} \mathrm{M}_{y}(\beta \text {-dik })_{2 x+2 y}$ ( $\mathrm{M}=\mathrm{Mn}, \mathrm{Co}, \mathrm{Ni}, \mathrm{Fe}, \mathrm{Zn}$ ) have been synthesized as single-source precursors (SSPs) for functional lead-containing transition-metal oxides or fluorides [1-3]. $\beta$-Diketonate ligands such as acetylacetonate (acac) and fluorinated hexafluoroacetylacetonate (hfac) and trifluoroacetylacetonate (tfac) have been employed to form heterometallic complexes that exhibit good volatility and solubility. More importantly, the ligands endowed the above SSPs with lowtemperature decomposition to produce target materials such as magnetoelectrics $\mathrm{Pb}_{2} \mathrm{MF}_{6}$ ( $\mathrm{M}=\mathrm{Ni}$ and Co ) $[1,4]$ or multiferrorics $\mathrm{Pb}_{2} \mathrm{Fe}_{2} \mathrm{O}_{5}[3,5]$. Most of the lead-transition metal $\beta$-diketonates appeared to have polymeric structures built upon combination of $\mathrm{Pb}(\beta \text {-dik })_{y}$ $(y=0,1,2)$ and $\mathrm{M}(\beta \text {-dik })_{x}(x=2,3)$ units connected by Lewis acid-base $\mathrm{Pb}-\mathrm{O} / \mathrm{M}-\mathrm{O}$ interactions (bridging bonds) with three different $\mathrm{Pb}: \mathrm{M}$ ratios of 2:1, 1:1, and 1:2 [1-3]. Within the heterometallic assemblies, lead and transition metals both exhibit coordination numbers of six with the former preferring cis-bridging and the latter trans-bridging with neighboring fragments [1-3,6-14]. In this work, we describe the synthesis and characterization of a new lead-containing heterobimetallic heptanuclear homoleptic complex $\left[\mathrm{Pb}_{2} \mathrm{Co}_{5}(\mathrm{acac})_{14}\right]$ which is distinguished from the previously reported $\mathrm{Pb}-\mathrm{M}$ compounds in several aspects. The ratio of $\mathrm{Pb}: \mathrm{Co}=2: 5$ is unique, while the heptanuclear structure is constructed by both cis- and trans-bridged $\left[\mathrm{Co}(\mathrm{acac})_{2}\right.$ ] units providing more complex/flexible coordination environment. Due to the good volatility, the $\left[\mathrm{Pb}_{2} \mathrm{Co}_{5}(\mathrm{acac})_{14}\right]$ complex is interesting as a prospective precursor in the metal-organic chemical vapor deposition (MOCVD) for the preparation of high-technological thin films with desired stoichiometry [15-17]. The
unusual lead:cobalt ratio makes it attractive to investigate the potential application for the low-temperature formation of lead-cobalt-coated anodes, lone-pair multiferrorics, and superconducting materials [18-27].

## 2. Materials and Methods

### 2.1. Materials and Measurements

Lead(II) acetylacetonate $\left[\mathrm{Pb}(\mathrm{acac})_{2}\right]$ and cobalt(II) acetylacetonate $\left[\mathrm{Co}(\mathrm{acac})_{2}\right.$ ] were purchased from Sigma-Aldrich and used as received after checking their powder X-ray diffraction patterns. The ICP-OES analysis was carried out on ICPE-9820 plasma atomic emission spectrometer, Shimadzu. The IR spectrum was measured using IRTracer-100 Fourier Transform Infrared Spectrophotometer, Shimadzu. The DART-MS spectra were recorded on AccuTof 4G LC-plus DART mass spectrometer, JEOL. X-ray powder diffraction data were collected on a Rigaku MiniFlex 6G benchtop diffractometer ( $\mathrm{Cu} \mathrm{K} \alpha$ radiation, D/teX Ultra silicon strip one-dimensional detector, step of $0.01^{\circ} 2 \theta, 20^{\circ} \mathrm{C}$ ). Le Bail fit refinement for powder diffraction patterns has been performed using TOPAS, version 4 software package (Bruker AXS, Billerica, MA, USA, 2006).

### 2.2. General Synthetic Procedures

The solid-state/gas phase synthesis of heterometallic complexes was carried out by grinding and sealing the stoichiometric mixture of starting reagents in an evacuated glass ampule and placing it into a gradient furnace. Solution synthesis of heterometallic complex was performed by adding dry and deoxygenated organic solvent to the stoichiometric mixture of starting reagents in a flask under a dry, oxygen-free argon atmosphere using standard Schlenk and glove box techniques. Detailed synthetic procedures are described in Section 3.1.

### 2.3. X-ray Crystallographic Procedures

The crystals of $\left[\mathrm{Pb}_{2} \mathrm{Co}_{5}(\mathrm{acac})_{14}\right]$ were immersed in cryo-oil, mounted on a glass fiber, and measured at the temperature of $100(2) \mathrm{K}$. The X-ray diffraction data were collected on a Huber Kappa system with a DECTRIS PILATUS3 X 2M(CdTe) pixel array detector using $\phi$ scans (synchrotron radiation at $\lambda=0.49594 \AA$ ) located at the Advanced Photon Source, Argonne National Laboratory (NSF's ChemMatCARS, Sector 15, Beamline 15-ID-D). The crystals of $\left[\mathrm{PbCo}(\mathrm{acac})_{4}\right]$ were immersed in cryo-oil, mounted on a loop, and measured at the temperature of $100(2) \mathrm{K}$. The X-ray diffraction data were collected on a Bruker D8 SMART diffractometer using Mo K $\alpha$ radiation. The dataset reduction and integration for both structures were performed with the Bruker software package SAINT (version 8.38A) [28]. The data were corrected for absorption effects using the empirical methods as implemented in SADABS (version 2016/2) [29]. The structures were solved by SHELXT (version 2018/2) [30] and refined by full-matrix least-squares procedures using the Bruker SHELXTL (version 2019/2) [31] software package through the OLEX2 graphical interface [32]. All non-hydrogen atoms were refined anisotropically. Hydrogen atoms were included in idealized positions for the structure factor calculations with $U_{\text {iso }}(\mathrm{H})=1.2 U_{\text {eq }}(\mathrm{C})$ and $U_{\text {iso }}(\mathrm{H})=1.5 U_{\mathrm{eq}}(\mathrm{C})$ for methyl groups. Crystallographic data and details of the data collection and structure refinement are listed in Table 1.

## 3. Results and Discussion

### 3.1. Synthesis and Properties of $\left[\mathrm{Pb}_{2} \mathrm{Co}_{5}(\mathrm{acac})_{14}\right]$ and $\left[\mathrm{PbCo}(\mathrm{acac})_{4}\right]$

Synthesis of heterometallic complex $\left[\mathrm{Pb}_{2} \mathrm{Co}_{5}(\mathrm{acac})_{14}\right]$ was carried out by both solidstate and solution approaches through the stoichiometric reaction (Equation (1)). For the solid-state synthesis, 10 mg of [ $\left.\mathrm{Pb}(\mathrm{acac})_{2}\right](0.025 \mathrm{mmol})$ and 16 mg of [Co(acac) $)_{2}$ ] $(0.062 \mathrm{mmol})$ were sealed in an evacuated glass ampule. The ampule was placed in a furnace with a temperature gradient of 130 to $120^{\circ} \mathrm{C}$. After one day of heating, block-shaped violet $\left[\mathrm{Pb}_{2} \mathrm{Co}_{5}(\mathrm{acac})_{14}\right]$ crystals were sublimed to the cold zone of the container ( 16 mg , ca. $62 \%$ yield). The product can be obtained in nearly quantitative yield by extending the reaction time to one week under the same conditions. Microcrystalline powder of $\left[\mathrm{Pb}_{2} \mathrm{Co}_{5}(\mathrm{acac})_{14}\right]$ was synthesized by dissolving 100 mg of $\left[\mathrm{Pb}(\mathrm{acac})_{2}\right](0.25 \mathrm{mmol})$ and 160 mg of [Co(acac) $)_{2}$ ( 0.62 mmol ) in 20 mL of dry and deoxygenated hexanes under argon atmosphere. The solution was stirred at room temperature for 1 day, resulting in a large amount of violet precipitate being formed. The solid was filtered off and dried under vacuum at $100^{\circ} \mathrm{C}$ sand bath overnight to afford the final product with a practically quantitative yield.

$$
\begin{equation*}
2 \mathrm{~Pb}(\mathrm{acac})_{2}+5 \mathrm{Co}(\mathrm{acac})_{2} \rightarrow \mathrm{~Pb}_{2} \mathrm{Co}_{5}(\mathrm{acac})_{14} \tag{1}
\end{equation*}
$$

The block-shaped violet crystals acquired from the solid-state reaction were first checked by the ICP-OES analysis, which revealed the metal ratio of $\mathrm{Pb}: \mathrm{Co}$ as $2: 5$, different from any previously investigated $\mathrm{Pb}_{x} \mathrm{M}_{y}(\beta \text {-dik) })_{2 x+2 y}$ complexes [1-3]. X-ray powder diffraction was applied to check the phase purity of the $\left[\mathrm{Pb}_{2} \mathrm{Co}_{5}(\mathrm{acac})_{14}\right]$ bulk products obtained from the solid state and solution methods (Figure 1). The Le Bail fit was performed to confirm that the experimental powder patterns of the bulk products correspond to the theoretical spectrum calculated from the single crystal X-ray data (Figure 1 and Table 2).

Figure 1. X-ray powder diffraction patterns of $(a)\left[\mathrm{Pb}_{2} \mathrm{Co}_{5}(\mathrm{acac})_{14}\right]$ bulk product obtained from the solution reaction and the Le Bail fit; $(\mathbf{b})\left[\mathrm{Pb}_{2} \mathrm{Co}_{5}(\mathrm{acac})_{14}\right]$ crystals obtained from the solid-state reaction and the Le Bail fit. In both pictures, blue and red curves represent experimental and calculated patterns, respectively. Gray is the differential curve with theoretical peak positions shown as red bars at the bottom.

Direct Analysis in Real Time (DART) mass spectrometry was performed to check the retention of heterometallic structure and analyze the ions in the gas phase. In the positive mode mass spectrum of $\left[\mathrm{Pb}_{2} \mathrm{Co}_{5}(\mathrm{acac})_{14}\right]$ (SI, Figure S 1 and Table S1) heterometallic ion peaks such as $\left[\mathrm{PbCo}_{3}(\mathrm{acac})_{7}\right]^{+},\left[\mathrm{PbCo}_{4}(\mathrm{acac})_{9}\right]^{+}$, and $\left[\mathrm{Pb}_{2} \mathrm{Co}(\mathrm{acac})_{5}\right]^{+}$that represent the fragmentation of the heptanuclear $\left[\mathrm{Pb}_{2} \mathrm{Co}_{5}(\mathrm{acac})_{14}\right]$ molecule can be clearly detected. All heterometallic ion fragments with relatively high intensities are measured precisely with the difference between measured and calculated $m / z$ being smaller than 0.006 and characteristic isotope distribution patterns (SI, Figure S1 and Table S1). The peak corresponding to heptanuclear ion $[\mathrm{M}-\mathrm{L}]^{+}\left(\mathrm{M}=\left[\mathrm{Pb}_{2} \mathrm{Co}_{5}(\mathrm{acac})_{14}\right], \mathrm{L}=a c a c\right)$ was not detected in the DART mass spectrum, indicating that the structure is quite fragile. In fact, this is the first heterometallic molecule in our research that was found not to feature the $[\mathrm{M}-\mathrm{L}]^{+}$peak in the positive mode, though we should notice that it is the heaviest so far to be investigated. At the same time, the fragment peaks unambiguously confirm the $(+2)$ oxidation states of both lead and cobalt.

The IR spectrum of $\left[\mathrm{Pb}_{2} \mathrm{Co}_{5}(\mathrm{acac})_{14}\right]$ was also recorded and shown in the SI, Figure S2. The $\left[\mathrm{Pb}_{2} \mathrm{Co}_{5}(\mathrm{acac})_{14}\right]$ complex is stable in the presence of oxygen in the solid state, but is quite sensitive to moisture. It has a good solubility in polar, weakly/non-coordinating solvents such as $\mathrm{CHCl}_{3}$ and $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ at room temperature, but shows a poor solubility in non-polar solvents such as hexanes, pentanes, cyclohexane, and toluene at room temperature. $\left[\mathrm{Pb}_{2} \mathrm{Co}_{5}(\mathrm{acac})_{14}\right]$ can be quantitatively sublimed at as low as $105^{\circ} \mathrm{C}$ under static vacuum conditions (sealed evacuated ampule) and starts to show the traces of decomposition when the temperature is raised to $150^{\circ} \mathrm{C}$.

The synthesis of heterometallic complex $\left[\mathrm{PbCo}(\mathrm{acac})_{4}\right]$ was carried out by the solidstate approach. First, 15 mg of $\left[\mathrm{Pb}(\mathrm{acac})_{2}\right](0.037 \mathrm{mmol})$ and 9 mg of $\left[\mathrm{Co}(\mathrm{acac})_{2}\right](0.035 \mathrm{mmol})$ were sealed in an evacuated glass ampule. The ampule was placed in a furnace with a temperature gradient of 115 to $105^{\circ} \mathrm{C}$. After one day of heating, block-shaped pink
crystals of $\left[\mathrm{PbCo}(\mathrm{acac})_{4}\right]$ were sublimed to the "cold" zone of the container ( 10 mg , ca. $42 \%$ yield). The differences in synthetic procedures for the preparation of $\left[\mathrm{Pb}_{2} \mathrm{Co}_{5}(\mathrm{acac})_{14}\right]$ and $\left[\mathrm{PbCo}(\mathrm{acac})_{4}\right]$ are the ratio of starting reagents and the temperature in the "hot" zone of the ampule. The crystal colors of two compounds are noticeably different. [ $\left.\mathrm{PbCo}(\mathrm{acac})_{4}\right]$ is structurally analogous to the previously reported $\left[\mathrm{PbM}(\beta \text {-dik })_{4}\right]$ compounds $(\mathrm{M}=\mathrm{Mn}$, Fe , and $\mathrm{Zn} ; \beta$-dik = acac, tfac, and hfac) [1-3] and was obtained for comparison of bond distances and coordination mode of Co ion, which are discussed in detail in Section 3.2.

### 3.2. Single Crystal Structure of $\left[\mathrm{Pb}_{2} \mathrm{Co}_{5}(\text { acac })_{14}\right]$

In this work, we used sterically uncongested $\beta$-diketonate ligand, acetylacetonate (acac), to synthesize a heterobimetallic assembly $\left[\mathrm{Pb}_{2} \mathrm{Co}_{5}(\mathrm{acac})_{14}\right]$, which contains both cis- and trans-bridging $\left[\mathrm{Co}(\mathrm{acac})_{2}\right]$ units. Single-crystal X-ray diffraction analysis revealed that the solid-state structure of this heterometallic complex contains discrete heptanuclear molecules with metal chain in an order of [ $\mathrm{Co}-\mathrm{Co}-\mathrm{Pb}-\mathrm{Co}-\mathrm{Pb}-\mathrm{Co}-\mathrm{Co}$ ]. The central Co 1 atom (Figure 2) sits on an inversion center; therefore, there are only four crystallographically independent metal sites (three Co and one Pb ) within the structural motif. Each metal center has two chelating acac ligands and fulfills its coordination environment by two additional contacts with oxygen atoms that are chelating its neighbors. The [M(acac) ${ }_{2}$ ] ( $\mathrm{M}=\mathrm{Co}, \mathrm{Pb}$ ) groups are connected through Lewis acid-base $\mathrm{M}-\mathrm{O}$ interactions of 2.09-2.26 and 2.81-2.86 A for Co and Pb ions, respectively (Tables 3 and 4), that are significantly shorter than the sum of the corresponding van der Waals radii. Although all metal centers have a coordination number of 6 , the coordination environments are distinctively different. Two outmost $\left[\mathrm{Co}(\mathrm{acac})_{2}\right]$ fragments offer only one acac oxygen each for the bridging interactions with the neighboring $\left[\mathrm{Co}(\mathrm{acac})_{2}\right]$ units, which, in turn, offer two acac oxygens for bridging interactions with the end-chain $\left[\mathrm{Co}(\mathrm{acac})_{2}\right]$ units in a cis-fashion and an additional acac oxygen to bridge the $\left[\mathrm{Pb}(\mathrm{acac})_{2}\right]$ unit. The bond distances for bridging $\mathrm{Co}-\mathrm{O}$ bonds in these units are between 2.09 and $2.22 \AA$, longer than chelating and chelating-bridging Co-O distances in the structural motif (Table 3). The cobalt atoms in these two units maintain a slightly distorted octahedral geometry with two acac ligand planes being almost perpendicular to each other. Since both cobalt centers in the [Co(acac) $)_{2}$ ] units appear as bis-cis-chelated, they are obviously chiral. The Co2 and Co3 exhibit the same chirality (either $\Delta, \Delta$ or $\Lambda, \Lambda)$. Considering the inversion center in the middle of this heptanuclear assembly, the compound is meso and does not feature diastereomers. In the central $\left[\mathrm{Co}(\mathrm{acac})_{2}\right]$ fragment, Co1 ion has two chelating acac ligands that are located in a plane, with two bridging Co-O interactions from the neighboring $\left[\mathrm{Pb}(\mathrm{acac})_{2}\right]$ units in a trans-configuration. Both acac oxygens from one of the ligand in the central [Co(acac) $)_{2}$ ] group are pure chelating, while those from the second ligand bridge to $\left[\mathrm{Pb}(\mathrm{acac})_{2}\right]$ groups on both sides. Since these two trans-bridging Co-O distances are much longer than those four from chelating bonds, the coordination of the central Co ion can be described as an axially elongated octahedral geometry. In the heptanuclear structure, the $\left[\mathrm{Pb}(\mathrm{acac})_{2}\right]$ units act as a glue to connect two $\left[\mathrm{Co}_{2}(\mathrm{acac})_{4}\right]$ fragments on both sides with the central [Co(acac) $\left.)_{2}\right]$ unit by two bridging interactions through one oxygen from each of two acac ligands. The $6 s^{2}$ lone electron pair of the lead repels two Pb -chelating acac ligands to be in a face-to-face fashion arrangement with a dihedral angle of $33.01^{\circ}$.

The appearance of both cis- and trans-bridging modes for the [Co(acac) ${ }_{2}$ ] units in $\left[\mathrm{Pb}_{2} \mathrm{Co}_{5}(\mathrm{acac})_{14}\right]$ makes it unique among polynuclear cobalt and heterometallic lead-cobalt $\beta$-diketonate complexes. Thus, the tetranuclear structure of $\left[\mathrm{Co}_{4}(\mathrm{acac})_{8}\right]$ (Figure 3) features only the cis-bridging mode to combine four $\left[\mathrm{Co}(\mathrm{acac})_{2}\right.$ ] monomers together [6]. In contrast, the polymeric heterometallic structure of $\left[\mathrm{PbCo}(\mathrm{acac})_{4}\right]$ (Figure 4) shows only trans-bridged $\left[\mathrm{Co}(\mathrm{acac})_{2}\right]$ building up the 1 D polymeric chain with $\left[\mathrm{Pb}(\mathrm{acac})_{2}\right]$ units in $1: 1$ ratio. Analogous $\beta$-diketonate $\left[\mathrm{PbCo}(\mathrm{hfac})_{4}\right][1]$ also has a polymeric structure but it is constructed by alternating $\left[\mathrm{Co}(\mathrm{hfac})_{3}\right]^{-}$and $[\mathrm{Pb}(\mathrm{acac})]^{+}$units. In turn, all $\left[\mathrm{Pb}(\mathrm{acac})_{2}\right]$ fragments in the lead-transition metal $\beta$-diketonate structures [1-3] are cis-bridging.

## 4. Conclusions

The heterobimetallic complex $\left[\mathrm{Pb}_{2} \mathrm{Co}_{5}(\mathrm{acac})_{14}\right]$ was synthesized by both solid-state and solution techniques and its unique heptanuclear molecular structure was revealed by synchrotron single-crystal X-ray diffraction. It was shown that the [Co(acac) $)_{2}$ ] units in the assembly exhibit both cis- and trans-bridging modes, which is different from previously reported polynuclear cobalt complexes and lead-transition metal $\beta$-diketonate coordination polymers. With high volatility and solubility, this heterometallic compound with unprecedented transition metal:lead ratio can serve as a precursor for the low-temperature preparation of prospective functional thin film materials such as lead-cobalt composite coating, lone-pair multiferroics, and superconductors. Importantly, this unique molecule with two distinctively different cobalt positions should be investigated as a model structure for the design of more complex heterotrimetallic compounds with partial substitution of cobalt with other divalent metals.

#### Abstract

Scorpiand-like ligands combine the preorganization of the donor atoms of macrocycles and the degrees of freedom of the linear ligands. We prepared the complexes of several of these ligands with transition metal ions and made a crystallographic and water solution speciation studies. The analysis of the resulting crystal structures show that the ligands have the ability to accommodate several metal ions and that the coordination geometry is mostly determined by the ligand. Ligand 6-[3,7-diazaheptyl]-3,6,9-triaza-1-(2,6)-pyridinacyclodecaphane (L3) is an hexadentate ligand that affords a family of isostructural crystals with $\mathrm{Cu}(\mathrm{II}), \mathrm{Mn}(\mathrm{II}), \mathrm{Ni}(\mathrm{II})$ and $\mathrm{Zn}($ II $)$. The attempts to obtain Co (II) crystals afforded the Co (III) structures instead. Ligand 6-[4-( 2-pyridyl)-3-azabutyl]-3,6,9-triaza-1(2,6)-pyridinacyclodecaphane (L2) is very similar to L3 and yields structures similar to it, but its behavior in solution is very different due to the different interaction with protons. Ligand 6-(2-aminoethyl)-3,6,9-triaza-1-(2,6)-pyridinacyclodecaphane (L1) is pentadentate and its complexes allow the metal to be more accessible from the solvent. A $\mathrm{Zn}(\mathrm{II})$ structure with $\mathbf{L 1}$ shows the species $[\mathrm{ZnBrHL} 1]^{2+}$, which exists in a narrow pH range.

Keywords: transition metals; metal ions; coordination chemistry; isostructural; scorpiand-like ligands

## 1. Introduction

Macrocyclic ligands offer an interesting framework for the study of coordination chemistry because all their donor atoms come preorganized, arranged geometrically in space. When they coordinate transition metals, the resulting coordination geometry is determined by the combined action of the preferred coordination geometry of the metal and the ability of the ligand to adapt to it. In the case of macrocyclic ligands, they tend to impose their coordination mode. If the ligand is open, linear and flexible, it has many more conformational degrees of freedom and, therefore, it is able to adapt to a wider variety of coordination preferences. It is possible to combine both types in a family of ligands that features a macrocyclic core decorated with a flexible pending arm containing additional donor atoms. Such ligands are often referred to as scorpiands due to its similarity with the body of a scorpion, where the macrocycle would be the scorpion body and the pending arm would be the tail with a sting at the end of it. They were first reported by Lotz and Kaden [1] although the name scorpiand was first coined by Fabrizzi and collaborators [2].

In our research group, we work with a family of ligands of this kind. Some of them are derivatives of L1 (see Figure 1), which can be readily obtained from a modified Richman-Atkins condensation of 2,6-bis(bromomethyl)pyridine with tris[2-( $N$-tolylsulpho-nylaminoethyl)]-amine followed by detosylation with HBr /acetic acid to obtain the hydrobromide salt [3]. L1 consists of a 12-membered ring with four nitrogen donor atoms: one is a pyridine nitrogen, two of them are secondary amino groups, and the last one is a tertiary amino group. This macrocycle is too small to equatorially coordinate a metal atom. Instead, when a metal atom goes into the cavity, the macrocycle folds leave two adjacent coordination vacancies as it can be seen in the literature in many examples that contain either L1 or the analog macrocycle without the pending arm [4-7]. This tendency to fold
makes the bonds around N2 and N4 (see numbering in Figure 1) stretched out if it is possible. This feature is relevant in order to understand the structures presented in this work. From the synthetic point of view, L1 contains a primary amino group, which allows to easily introduce additional moieties in that position. A sizable number of derivatives of L1 containing different groups in that position have been synthesized and reported by our group [3,8-10]. When L1 is reacted with 2-pyridinecarboxaldehyde, we obtain the ligand L2, which incorporates a sixth donor nitrogen atom in the pending arm. If the reagent is 3-bromopropylphthalimide followed by phthalimide cleavage with hydrazine, we obtain L3, which also features a sixth donor atom but is much more flexible than the analog L2.

L2

L3

Figure 1. Ligands used in this work and nitrogen atom numbering.
These ligands are able to coordinate many types of metal atoms, mainly transition and post-transition metal ions. So far, we reported interactions with $\mathrm{Cu}, \mathrm{Mn}, \mathrm{Zn}, \mathrm{Fe}$ and $\mathrm{Pb}[3,9,11-13]$, and research is underway with other metal ions as well. We focused on the copper and manganese complexes of these ligands because they show very interesting redox properties. When the metal in question is able to catalyze one-electron redox reactions, such as $\mathrm{Cu}(\mathrm{II})$ or $\mathrm{Mn}(\mathrm{II})$, we report that such complexes are able to mimic the redox cycle of superoxide dismutase (SOD), catalyzing the dismutation of the superoxide anion $[8,9,11]$ Iron complexes of $\mathbf{L} 2$ undergo oxidative dehydrogenation by the effect of a pH change [13]. These kinds of metal complexes might seem simple at first glance, but they exhibit a rather complex chemistry. Herein, we aim to present some of the features of this family of complexes by showing both solution and solid-state data in order to illustrate the interesting coordination chemistry that they exhibit.

## 2. Materials and Methods

### 2.1. Synthesis and Materials Used

The synthesis of $\mathbf{L 1}$, $\mathbf{L 2}$ and $\mathbf{L 3}$ was carried out as described in the literature $[3,8,9]$ For crystal preparation and potentiometric measurements, stock solutions ca. 0.1 M of either $\mathrm{MnSO}_{4} \cdot \mathrm{H}_{2} \mathrm{O}, \mathrm{Cu}\left(\mathrm{ClO}_{4}\right)_{2} \cdot 6 \mathrm{H}_{2} \mathrm{O}, \mathrm{Ni}\left(\mathrm{ClO}_{4}\right)_{2} \cdot 6 \mathrm{H}_{2} \mathrm{O}, \mathrm{Zn}\left(\mathrm{ClO}_{4}\right)_{2} \cdot 6 \mathrm{H}_{2} \mathrm{O}$ or $\mathrm{CoCl}_{2} \cdot 2 \mathrm{H}_{2} \mathrm{O}$ were prepared in Mili-Q water. The metal concentration was standardized by a suitable complexation volumetry method. In the particular case of iron stock solutions, they were prepared from $\mathrm{FeSO}_{4} \cdot 7 \mathrm{H}_{2} \mathrm{O}$ in 0.1 M HCl . In these cases, both the metal concentration and the acid concentration were determined by volumetric titration. The complexes were prepared by the simple mixing of equimolar amounts of both the metal stock solution and the desired ligand in an aqueous solution. Single crystals were prepared by the slow evaporation of a pH neutral water solution of the corresponding complex. Caution: Perchlorates are potentially explosive if they come in contact with organic matter, and they should be handled with extreme care.

### 2.2. X-ray Single Crystal Diffractometry

Single crystal X-ray diffraction was carried out with either of the following machines: (1) Enraf-Nonius KAPPA CCD single-crystal diffractometer with Mo $K_{\alpha}$ radiation $(\lambda=0.71073 \AA)$ and a graphite monochromator with data collection by COLLECT software with utilities DENZO and SCALEPACK, or (2) Agilent Super-Nova Diffractometer with
$\mathrm{Mo}_{\alpha}$ radiation $(\lambda=0.71073 \AA)$ with a mirror monochromator located at the Institute of Molecular Sciences (ICMOL) from the University of Valencia, and data acquisition and treatment performed with CRYSALISPRO software [14]. If an absorption correction needed to be applied, either a spherical absorption correction as implemented in DENZO, or a semi-empirical absorption correction (MULABS [15] as implemented in PLATON [16]) was applied.

Crystals were measured at room temperature ( 293 K ). The structures were solved initially with SHELXS [17] with direct methods. Then, they were refined with SHELXL [17] using OLEX2 [18] as the frontend. Final figures for publishing were produced using CHIMERA [19] or MERCURY [20].

### 2.3. Potentiometric Measurements

The potentiometric titrations were carried out in a thermostated bath at 298.1 K , using $\mathrm{NaClO}_{4} 0.15 \mathrm{M}$ as the supporting electrolyte, in the pH range 2.5-11.0. The experimental procedure (burette, potentiometer, cell, stirrer, microcomputer, etc.) is fully described elsewhere [21]. The acquisition of the electromotive force emf data was performed with the computer program PASAT $[22,23]$. The reference electrode was an $\mathrm{Ag} / \mathrm{AgCl}$ electrode in saturated KCl solution. The glass electrode was calibrated as a hydrogen ion concentration probe by titration of previously standardized amounts of HCl with carbonate-free NaOH solutions and the equivalent point determined by the Gran's method [24,25], which gives the standard potential $E^{\ominus}$ and the ionic product of water ( $\mathrm{p} K_{\mathrm{w}}=13.73(1)$ ). At least two reproducible titrations for each system were recorded. The computer program HYPERQUAD [26] was used to fit protonation and stability constants. The independent titration curves were treated first as separate curves, and then the curves for each system (at least two) were then merged and treated as a single set without significant variations in the values of those treated first as separate curves and then merged and treated as a single set without stability constants. The final values were those obtained from the simultaneous treatment of the merged curves. The HYSS [27] program was used to generate the distribution diagrams.

## 3. Results and Discussion

### 3.1. Interaction of $\mathbf{L 3}$ with $\mathrm{Mn}, \mathrm{Fe}, \mathrm{Co}, \mathrm{Cu}, \mathrm{Ni}$ and Zn

L3 has six donor atoms that can be geometrically arranged in an octahedral disposition. When a metal atom is placed inside the ligand cavity, the ligand itself will impose its preferred coordination geometry rather than the metal. We prepared crystals of L3 with several transition and post-transition metals and successfully solved the structures for $\mathrm{Mn}(\mathrm{II}), \mathrm{Cu}(\mathrm{II}), \mathrm{Ni}(\mathrm{II})$ and $\mathrm{Zn}(\mathrm{II})$ with $\mathrm{ClO}_{4}^{-}$counterions. We named these structures C 1 to C4, respectively. Unfortunately, crystals of L3 with iron could not be obtained. Also, for the case of the Co (II) complex, the Co (III) structure was obtained instead. This ligand readily coordinates metal ions. We studied some metal atoms from the first transition series for their biological relevance. We previously reported copper- or manganese-related crystal structures [9-11], but we include some of them here again for comparative purposes.

We studied metal complex formation in solution and we fitted the values of the formation constants. The results are summarized in Table 1 . The stability constant values follow the expected order: $\mathrm{Mn}<\mathrm{Fe}<\mathrm{Cu}>\mathrm{Zn}$. All of them form stable complexes with L3. In addition to that, several protonation constants for each complex were also found and refined with up to three protons. The values of the first protonation constants lie between 4.59 for $\mathrm{Cu}(\mathrm{II})$ and 8.14 for Fe (II). This indicates that above pH ca. 8 , the complex should be completely hexacoordinated. Distribution diagrams show that the species $[\mathrm{ML}]^{2+}$ is completely formed in those conditions. Indeed, we obtained all the crystals for L3 from moderately alkaline solutions. Also, some hydroxylated species were also found in the speciation study, but they only predominate at $\mathrm{pH}>11$. Solution studies with $\mathrm{Ni}(\mathrm{II})$ were also carried out, but the slow kinetics prevented the fitting of reliable formation constants. Nonetheless, suitable single-crystals were obtained from the solutions used in potentiometric measurements. Similarly, solution studies with Co(II) were also carried out,
but the values obtained do not match the expected results probably due to the oxidation that happens during the titration, preventing the collection of reliable data.

Table 1. Formation constants for L3 with some metal ions from the first transition series.

| Reaction ${ }^{1}$ | $\mathrm{Mn}(\mathrm{II})^{2}$ | Fe (II) | $\mathrm{Cu}(\mathrm{II})$ | Zn (II) |
| :---: | :---: | :---: | :---: | :---: |
| $\mathrm{MH}_{2} \mathbf{L}+\mathrm{H} \rightleftharpoons \mathrm{MH}_{3} \mathbf{L}$ | - | $6.35(7)^{3}$ | 3.1(2) | 4.26(6) |
| MHL $+\mathrm{H} \rightleftharpoons \mathrm{MH}_{2} \mathrm{~L}$ | 5.79(9) | 5.87(5) | 3.59 (7) | 5.32(3) |
| ML $+\mathrm{H} \rightleftharpoons$ MHL | 7.74(1) | 8.17(2) | 4.47(2) | 6.27 (3) |

${ }^{1}$ Charges omitted. ${ }^{2}$ Values from ref [9]. ${ }^{3}$ Values represent $\log _{10} K$, values in parentheses represent standard deviation of the last significant figure.

Crystals C1-C4 are isostructural (Figure 2a-d) with the same orthorhombic crystal system, Pbca space group and atom arrangement, with the only difference being the metal atom coordinated to the ligand. Bond distances and angles are shown in Table A4. We always find that the longest bond distances involve N2 and N4. These two donor atoms are the ones that have to stretch more in order to coordinate a metal located inside the macrocycle. When the metal in question displays Jahn-Teller distortion, such as Cu (II) (crystal C2, Figure 2b), then the elongated axis is N2-M—N4 so that the bonds around N2 and N4 are in a more relaxed conformation. Some others, like $\mathrm{Zn}(\mathrm{II})$, do not have Jahn-Teller distortion but still have the axis N2—M—N4 as being slightly longer. This indicates that the coordination geometry is to a large extent imposed by the ligand and only to a lesser extent by the metal atom. The metal atom, though, also exerts some influence; that is why the length difference between the axial and equatorial bonds is larger for $\mathrm{Cu}(\mathrm{II})$ than for Zn (II). In these four structures, the packing is mainly ionic. In Figure 2e, details of the packing of $\mathbf{C 1}$ show the arrangement of anions and cations in the unit cell. It is worthwhile noting that in all these structures, the metal ion is completely wrapped and enclosed by the ligand, leaving no vacant coordination sites and restricted access to the metal from the solvent. This is best seen in Figure 2f, where the spacefill representation shows that the metal ion is not accessible from the solvent. This feature explains that Mn (II) complexes are not oxidized in alkaline conditions open to air, and crystals containing Mn(II) are obtained. When crystals are prepared from a neutral solution of $[\mathrm{MnL1}]^{2+}$, then a structure containing $\mathrm{Mn}(\mathrm{III})$ is obtained, which consists of two units of $[\mathrm{MnL1}]^{3+}$ bridged by an oxo anion [28].

Figure 2. (a-d) Asymmetric unit of structures $\mathrm{C} 1-\mathrm{C} 4$ featuring $\mathrm{Mn}(\mathrm{II}), \mathrm{Cu}(\mathrm{II}), \mathrm{Ni}(\mathrm{II})$ or $\mathrm{Zn}(\mathrm{II})$, respectively. (e) Packing of $\mathbf{C 1}$ with $[\mathrm{CuL3}]^{2+}$ depicted in red, and perchlorate anions in blue. (f) Spacefill of $\mathbf{C} 4$ highlighting the inaccessibility of the metal atom from the solvent.

### 3.2. Cobalt Complexes of L1 and L3

When a pale pink, diluted solution of $[\mathrm{CoL} 3]^{2+}$ in aqueous $\mathrm{NaClO}_{4}$ was allowed to slowly evaporate, deep blue crystals of $[\mathrm{CoL} 3]\left(\mathrm{ClO}_{4}\right)_{3}\left(\mathrm{H}_{2} \mathrm{O}\right)$ were obtained instead of the expected Co (II) ones. As we noted above, the metal atom inside the cavity was completely enclosed by the ligand, which provides protection against air oxidation for the Mn (II) complexes. This seems not to be the case for $\mathrm{Co}(\mathrm{II})$, as we consistently obtained the crystal with Co (III). As mentioned above, speciation studies under argon were carried out, but the obtained formation constants are not reported herein, as the oxidation appears to happen to some extent during the titration process, which makes the values unreliable. A similar thing also happens when $\mathrm{Co}(\mathrm{II})$ complexes of $\mathbf{L 1}$ are allowed to slowly evaporate: single crystals containing the $[\mathrm{CoBrL1}]^{2+}$ complex are obtained. Two different structures containing this complex were resolved: firstly, crystal C 6 with formula $[\mathrm{CoBrL1}] \mathrm{Br}_{2}\left(\mathrm{H}_{2} \mathrm{O}\right)$, and crystal C 7 with formula $[\mathrm{CoBrL1}] \mathrm{Na}\left(\mathrm{ClO}_{4}\right)_{3}$ in which sodium perchlorate is co-crystallized along with the complex. In all three examples, the $\mathrm{Co}(\mathrm{II})$ atom is easily oxidized to $\mathrm{Co}(\mathrm{III})$ by exposure to the atmosphere. The geometry of the complex $[\mathrm{CoBrL1}]^{2+}$ from $\mathbf{C} 6$ and that of the complex $[\mathrm{CoL} 3]^{3+}$ from $\mathbf{C} 5$ are shown in Figure 3a,b. The complex from $[\mathrm{CoBrL1}]^{2+}$ from C7 is not shown, but it is identical to that from C6. In all three structures, the Co (III) complex displays an octahedral coordination geometry, fairly regular with angles close to $90^{\circ}$ (see Table A5). In the case of C6 and C7, the sixth coordination site is occupied by a bromide atom, which exhibits a longer bond than the others (ca. $2.3 \AA$ ), which is to be expected since it is an atom bigger than the other ones. The complex from structure $\mathbf{C 7}$ is essentially identical to that of C6 with bonds and angles that are only slightly different (see Table A5). As occurs for C1-C4, the metal atom is deeply embedded, and it has no access from the solvent. In this case, a single water molecule is found in the asymmetric unit along with three perchlorate anions. Structure C6 contains a rich network of hydrogen bonds involving the hydrogen atoms of the amino groups, the water moiety and the bromide atoms (see Figure 3c). This structure is not purely electrostatic, but also the hydrogen bonds contribute to the packing. The water molecule is placed between two bromide atoms, Br2 and Br 3 , to which it donates hydrogen bonds, while not accepting from any other moiety All N-H groups are hydrogen bond donors towards the nearest bromide anion. C 7 is similar to $\mathbf{C} 6$, but it features an anionic moiety of $\left(\mathrm{Na}\left(\mathrm{ClO}_{4}\right)_{3}\right)_{n}^{2 n-}$ that grows along the $b$ crystallographic axis. Units of $[\mathrm{CoBrL1}]^{2+}$ cations are placed in alternating orientation, filling in the gaps (see Figure 3d). This structure has a bigger electrostatic contribution to the packing but still some relevant hydrogen bonds are found (see Table A8).

Figure 3. (a) Details of the complex $[\mathrm{CoBrL1}]^{2+}$ from C6. Hydrogen atoms not shown. (b) Detail of the complex $[\mathrm{CoL} 3]^{3+}$ from C5. Hydrogen atoms not shown. (c) Unit cell of $\mathbf{C} 6$ shown along the $b$-axis, displaying the packing and the internal hydrogen bonding structure. Hydrogen atoms not shown. (d) Unit cell of $\mathbf{C 7}$ shown along the $b$-axis with Na atoms displayed in polyhedral, carbon atoms in capped stick representation, and other atoms displayed in ball-and-stick. Hydrogen atoms not shown.

### 3.3. Complexes of $\mathbf{L} 2$ with $\mathrm{Cu}(I I)$ and $\mathrm{Mn}(I I)$

From the coordination point of view, L2 and L3 are similar because the two of them are hexadentate with the donor atoms in the same positions with the same number of bonds separating one from another. The only difference is that the donor $\mathbf{N}$ of $\mathbf{L} 2$ is on a rigid aromatic group and, for $\mathbf{L} 3$, it is located on a flexible aliphatic amino group. Indeed, the slow evaporation of an aqueous solution of the ligand with one equivalent of either $\mathrm{Cu}\left(\mathrm{ClO}_{4}\right)_{2}$ or $\mathrm{Mn}\left(\mathrm{ClO}_{4}\right)_{2}$ yields single crystals of either [ML2] $\left(\mathrm{ClO}_{4}\right)_{2}$ ] ( C 1 and C 2 ) and [ML3] $\left(\mathrm{ClO}_{4}\right)_{2}$ ] ( $\mathbf{C 8}$ and $\mathbf{C} 9$ ). The coordination mode is almost identical, as it can be seen comparing Figure 2a,b with Figure 4a,b. C1, C2, C8 and C9 crystallize in an orthorhombic system with very similar asymmetric units containing only one molecule of the complex, two perchlorate anions and no water molecules. The space group is different: C1 and C2, which contain L3, have a Pbca space group, while structures C8 and C9 have Pna2 ${ }_{1}$. Indeed, C8 is isostructural with $\mathbf{C} 9$ as $\mathbf{C 1}$ is to $\mathbf{C} 2$. This indicates that the metal exerts little influence outside the complex with regard to the packing. Another similarity is that the packing is mainly electrostatic as it can be seen in Figure 4c. The bond distances and angles are listed in Table A6. We observe, as we did for L3, the recurring feature that the longest metal-nitrogen bond distance involves N 2 and N 4 . This is very clear for $\mathbf{C 8}$, which contains $\mathrm{Cu}(\mathrm{II})$. For $\mathbf{C} 9$, which contains $\mathrm{Mn}(\mathrm{II})$, the bond Mn1-N5 is slightly longer than Mn1-N4. A possible explanation for this is that the angles for $\mathbf{C} 9$ are more distorted and further from $90^{\circ}$ than for C8.

Figure 4. (a) Details of the complex $[\mathrm{MnL2}]^{2+}$ from C8. (b) Details of the complex $[\mathrm{CuL2}]^{2+}$ from C9. (c) Unit cell of C 8 viewed down c axis. Hydrogen atoms omitted. Mn (purple), Cl (green), O (red), N (blue), C (gray).

If we explore the chemistry in solution, the similarities end, and we see very different behavior compared to the crystal state. Above, in Table 1, we show the formation constants of $\mathbf{L} 3$ with $\mathrm{Cu}(\mathrm{II})$. If we study the speciation of $\mathbf{L} 2$ with $\mathrm{Cu}(\mathrm{II})$, a single constant is found, with value $\log _{10} K_{\mathrm{CuL}}=22.6(1)$ [29]. This value is very close to that from L3 $\left(\log _{10} K_{\text {CuL }}=22.93(2)\right.$, see Table 1). Only this single constant is found, and its large value makes it possible for the species $[\mathrm{CuL}]^{2+}$ to be formed at low pH values and predominate in a very large pH range (Figure 5left). This is also the reason for the larger error in the constant: only a small set of points at low pH values contain meaningful information about the formation of the complex (see Figure 5left). Nonetheless, the obtained value is confirmed by means of titration with a competing ligand in order to increase the number of data points [29]. For L3, on the other hand, even though the formation constant with $\mathbf{C u}(\mathrm{II})$ is close to that of $\mathbf{L 2}$, the primary amino group can protonate more easily. As a result,
the $\mathrm{Cu}(\mathrm{II})$ atom is introduced at ca. one unit of pH higher, and the species $[\mathrm{CuL3}]^{2+}$ is not completely formed until $\mathrm{pH} \sim 6$ (Figure 5right).

Figure 5. Species distribution diagram for the system $\mathrm{Cu}(\mathrm{II})$ with $\mathbf{L} 2$ (left) and $\mathbf{L} 3$ (right) with $\left[\mathrm{Cu}^{2+}\right]=[\mathrm{L}]=1 \times 10^{-3} \mathrm{M}$. Charges omitted.

### 3.4. Complex of $\mathbf{L 1}$ with $\mathrm{Zn}(\mathrm{II})$

L1 is a good ligand for many transition metal atoms, such as Cu (II) [3], Mn (II) [28] or $\mathrm{Zn}(\mathrm{II})$ [12]. Usually in all the crystal structures of $\mathbf{L 1}$ reported by us, the metal atom is pentacoordinated with all donor atoms bonding the metal. Solution studies indicate that the complex $[\mathrm{ZnL1}]^{2+}$ can take one or two protons to form species $[\mathrm{ZnHL1}]^{3+}$ and $\left[\mathrm{ZnH}_{2} \mathrm{~L} 1\right]^{4+}[12]$.

We were able to obtain single crystals of one such species, $[\mathrm{ZnHL1}]^{3+}$. This structure, named C10, is shown in Figure 6. The terminal amino group can be protonated more easily than the other amino groups, and that coordination bond can break. In this case, the tip of the tail would be +1 , while the metal next to it is +2 . Therefore, the tail would fold away from the metal, giving, as a result, an open conformation, with the metal much more exposed to the solvent. C10 presents a triclinic Pī system and space group, and its asymmetric unit contains the complex $[\mathrm{ZnBrHL} 1]^{2+}$ with one water molecule and one $\mathrm{ZnBr}_{4}^{2-}$ counterion. In the unit of $[\mathrm{ZnBrHL1}]^{2+}$, the $\mathrm{Zn}(\mathrm{II})$ is pentacoordinated by the nitrogen atoms of $\mathbf{L 1}$, except N5, which is protonated, bearing one positive charge and being folded away from the metal atom, thus minimizing the electrostatic repulsion. The macrocycle is only partly folded as if it was trying to equatorially coordinate the metal ion but, being too small to do it, it stops halfway. The aforementioned electrostatic repulsion may also contribute to this conformation. N5 would be the fifth donor atom, but instead, a bromide anion fills this vacancy. The units of $[\mathrm{ZnBrHL} 1]^{2+}$ are grouped in pairs that share two hydrogen bonds between N4 and Br1 (see Figure 6b). A total of six hydrogen bonds can be located around each unit of complex. The details are shown in Table A9. Both electrostatic and hydrogen bonds are the main forces in the packing. The origin of $\mathrm{ZnBr}_{4}{ }^{2-}$ is the free metal available at $\mathrm{pH} \sim 5$, where the complex is not completely formed and the bromide counterions are from the $\mathbf{L} 1$ hydrobromide salt.

Figure 6. (a) Details of the complex $[\mathrm{ZnBrHL1}]^{2+}$ from C10. (b) Hydrogen bonding network around the complex.

## 4. Conclusions

The ligands presented herein have the ability to coordinate a variety of metal ions. We focused on metals from the first transition series and showed examples of $\mathrm{Cu}(\mathrm{II}), \mathrm{Mn}(\mathrm{II})$, Co (III), and $\mathrm{Ni}($ II $)$, as well as the post-transition metal ion $\mathrm{Zn}(\mathrm{II})$. The overall packing is mostly determined by the ligand. The same ligand with different metal atoms tends to yield either isostructural or structurally similar crystals provided that the charge does not change. L2 and L3 have almost the same coordination geometry and, as a consequence, the structures they afford are very similar. However, solid-state structures and solution studies show different pictures about the properties of the complexes due to the different interaction of the ligands with protons as it can be seen by comparing the speciation of $\mathrm{Cu}(\mathrm{II})$ and $\mathrm{Mn}(\mathrm{II})$ with either $\mathbf{L 2}$ or L3. L1, which is pentadentate, leaves the metal atom more exposed to the solvent.

#### Abstract

The application of a bidentate aromatic $N, N^{\prime}$-donor ligand, 2, $2^{\prime}$-biimidazole $\left(\mathrm{BIIMH}_{2}\right)$, as an extractant in the form of 1-octyl-2, $2^{\prime}$-biimidazole (OBIIMH) and related derivatives in the solvent extraction of base metal ions $\left(\mathrm{Mg}^{2+}, \mathrm{Mn}^{2+}, \mathrm{Fe}^{3+}, \mathrm{Fe}^{2+}, \mathrm{Co}^{2+}, \mathrm{Ni}^{2+}, \mathrm{Cu}^{2+}\right.$ and $\left.\mathrm{Zn}^{2+}\right)$ from an acidic sulfonate medium using dinonylnaphthalene disulfonic acid (DNNDSA) as a synergist was investigated. OBIIMH with DNNDSA as a co-extractant showed a lack of selectivity for base metals ions $\left(\mathrm{Mg}^{2+}, \mathrm{Mn}^{2+}, \mathrm{Fe}^{3+}, \mathrm{Fe}^{2+}, \mathrm{Co}^{2+}, \mathrm{Ni}^{2+}, \mathrm{Cu}^{2+}\right.$ and $\left.\mathrm{Zn}^{2+}\right)$ despite its similarity with a related bidentate aromatic ligand, $2,2^{\prime}$-pyridylimidazole, which showed preference for $\mathrm{Ni}(\mathrm{II})$ ions. The nickel(II) specificity, through stereochemical "tailor-making", was not achieved as expected and the extracted species were isolated to study the underlying chemistry. The homemade metal sulfonate salts, $\mathrm{M}\left(\mathrm{RSO}_{3}\right)_{2} \cdot 6 \mathrm{H}_{2} \mathrm{O}\left(\mathrm{R}=\right.$ Toluene and $\mathrm{M}^{2+}=\mathrm{Co}^{2+}, \mathrm{Ni}^{2+}, \mathrm{Cu}^{2+}$ and $\left.\mathrm{Zn}^{2+}\right)$, were used as precursors of the metal complexes of $\mathrm{BIIMH}_{2}$ using toluene-4-sulfonic acid as the representative sulfonate. Spectroscopic analysis and single-crystal X-ray analysis supported the formation of similar neutral distorted octahedral sulfonato complexes through the bis coordination of $\mathrm{BIIMH}_{2}$ and two sulfonate ions rather than the formation of cationic complex species with anion coordination of sulfonates. We attributed the observation of similar complex species and the similar stability constants of the bis-complexes in solution as the cause for the lack of pH -metric separation of the later 3d metal ions.

Keywords: solvent extraction; 2,2'-biimidazole; coordination chemistry; crystal structures

## 1. Introduction

The application of amine extractants in the neutral form has not been extensively explored as separating agents for base metal ions from a basic bonding viewpoint [1]. Strong ligands with an O-donor-only character show a lack of relative preference for the base metal ions while nitrogenous ligands show promise. Aromatic nitrogenous ligands have a relative preference for metal ions which could relate to the possibility of $\sigma$ and $\pi$ bonding [2]. Imidazole ligands/extractants show high-formation constants with later 3d-transition metals [1,3], resulting in high extraction efficiencies and interactions with these metals in slightly strongly to weakly acidic media since their protonation constants are not too high or too low. However, large counterions such as organic sulfonates which act as synergists in the extraction of cationic complexes are frequently employed for a solvent extraction system to facilitate the transfer of the complexes efficiently to the organic phase [4].

A bidentate ligand, 2,2'-biimidazole (Figure 1A), has been used for the extraction of base metals in this study. The high complex formation offered by the bidentate ligand and the low protonation constant of the imidazole group compared with aliphatic amines allows for the formation of the inner sphere complexes in a highly acidic medium. These characteristics were to be exploited in this study in an analogous matter to the use of $2,2^{\prime}-$ pyridylimidazole that we have studied previously [3]. It is anticipated that specificity for
base metal ions could be achieved through stereochemical "tailor-making", i.e., through the formation of complexes of different but preferred geometries. The outcome of this particular study is rather surprising, and we attempt to explain it from a basic chemistry point of view. Sulfonates are typically used as synergistic counterions to extract cationic complexes in solvent-extraction systems. However, this account presents their non-innocent nature towards inner sphere rather than outer sphere coordination in the complex formation of extracted species in a solvent-extraction system.

## (A)

(B)

Figure 1. The chemical structures of (A) 2,2'-biimidazole $\left(\mathrm{BIIMH}_{2}\right)$ and (B) dinonlynapthalene disulfonic acid (DNNDSA).

The alkylated derivatives of the bidentate $N, N$-donor $2,2^{\prime}$-biimidazole ligand were investigated for their selectivity for nickel(II) from other base metals along with dinonylnaphthalene disulfonic acid (DNNDSA) as a synergist (Figure 1B) in a solvent-extraction system. The conditions for the extraction studies were designed using the OBIIMH (octyl derivative) as an extractant and DNNDSA as a synergist; both were dissolved in $80 \%$ 2 -octanol and $20 \%$ Shellsol 2325 as diluent and modifier, respectively. The underlying coordination chemistry was investigated through stability constants studies and molecular structures of model-extracted species via spectroscopic techniques and single crystal X-ray crystallography. Herein, we concluded on the non-innocent nature of the sulfonates as synergistic counterions by showing evidence of inner sphere coordination.

## 2. Materials and Methods

### 2.1. Reagents and Materials

The reagents and materials used in this study, including ammonium acetate (99\%), 1-Bromodecane (99\%), 1-Bromoheptane (99\%), 1-Bromooctane (99\%), $\mathrm{CaSO}_{4} \cdot \mathrm{H}_{2} \mathrm{O}$ ( $98.5 \%$ ), $\mathrm{Co}\left(\mathrm{ClO}_{4}\right)_{2} \cdot 6 \mathrm{H}_{2} \mathrm{O}(98 \%), \mathrm{CoSO}_{4} \cdot 7 \mathrm{H}_{2} \mathrm{O}(97.5 \%), \mathrm{CdSO}_{4} \cdot \mathrm{H}_{2} \mathrm{O}(98 \%), \mathrm{Cu}\left(\mathrm{ClO}_{4}\right)_{2} \cdot 6 \mathrm{H}_{2} \mathrm{O}(98 \%)$, $\mathrm{CuSO}_{4}$ (anhydrous) (99\%), DNNDSA (55 wt \% in Iso-butanol), $\mathrm{Fe}_{2}\left(\mathrm{SO}_{4}\right)_{3} \cdot x \mathrm{H}_{2} \mathrm{O}(70 \%)$, $\mathrm{Fe}\left(\mathrm{SO}_{4}\right) \cdot 7 \mathrm{H}_{2} \mathrm{O}(98 \%)$, Glyoxal ( $40 \mathrm{wt} \%$ in water), $\mathrm{MgSO}_{4} \cdot 7 \mathrm{H}_{2} \mathrm{O}$ (99.7\%), $\mathrm{MnSO}_{4} \cdot 7 \mathrm{H}_{2} \mathrm{O}$ (99.2\%), $\mathrm{Ni}\left(\mathrm{ClO}_{4}\right)_{2} \cdot 6 \mathrm{H}_{2} \mathrm{O}(98 \%), \mathrm{NiSO}_{4} \cdot 6 \mathrm{H}_{2} \mathrm{O}(98 \%)$, Shellsol 232), Toluene-4-sulfonic acid ( $98 \%$ ), $\mathrm{Zn}\left(\mathrm{ClO}_{4}\right)_{2} \cdot 6 \mathrm{H}_{2} \mathrm{O}(98 \%), \mathrm{ZnSO}_{4} \cdot 7 \mathrm{H}_{2} \mathrm{O}$ (99.5\%), Acetone (98\%), Diethylether (99\%), Ethanol (99\%), Ethyl acetate (98.8\%), $\mathrm{H}_{2} \mathrm{SO}_{4}$ (98\%), Methanol (99.9\%) and 2-Octanol (98\%), were purchased from Sigma-Aldrich, South Africa. All solvents were purchased from Merch and used as received. Standard solutions of the metal ions of AAS calibration were prepared from 1000 ppm stock solutions in 0.5 M nitric acid supplied by EC lab services from South Africa.

### 2.2. Instrumentation

The purity and identity of the extractants were determined by using ${ }^{1} \mathrm{H}$ NMR spectroscopy on a Bruker AMX 400 NMR MHz spectrometer and reported relative to tetramethylsilane ( $\delta 0.00$ ). The metal complexes were characterized using infrared spectroscopy on both Perkin Elmer 400 FTIR and 100 FTIR-ATR spectrometers. The metal complexes were characterized using infrared spectroscopy and recorded on either a Perkin Elmer 400FTIR spectrometer in the mid-IR range $\left(400-4000 \mathrm{~cm}^{-1}\right)$ as KBr pellets or as neat compounds with a Perkin Elmer 100 FTIR-ATR ( $650-4000 \mathrm{~cm}^{-1}$ ) spectrometer. The solid reflectance spectra of ligands and complexes were recorded on a Shimadzu UV-VIS-NIR Spectrophotometer UV-3100 with an MPCF-3100 sample compartment with samples mounted between two quartz discs that fit into a sample holder coated with barium sulfate. The spectra were
recorded over the wavelength range of 250-1400 nm, and the scans were conducted at a medium speed using a 20 nm slit width.

Elemental analysis was carried out with a Vario Elementary ELIII Microcube CHNS elemental analyser. A Perkin-Elmer 603 atomic absorption spectrophotometer, with a burner control attachment and an air-acetylene flame, was used for the determination of metal ions' concentrations after extraction. The AAS metal standards, dissolved in 0.5 N nitric acid, were used to prepare standard solutions for the construction of calibration curves using 0.002 M ethylenediaminetetraacetic acid (EDTA) solution for the dilutions. The EDTA was also used to dilute the samples to prevent formation of refractory $\mathrm{NiSO}_{4}$. The elements were analysed at the following specified wavelengths ( nm ) for minimal interferences: $232.0\left(\mathrm{Ni}^{2+}\right)$, $240.7\left(\mathrm{Co}^{2+}\right), 324.7\left(\mathrm{Cu}^{2+}\right), 213.9\left(\mathrm{Zn}^{2+}\right), 248.3\left(\mathrm{Fe}^{2+}, \mathrm{Fe}^{3+}\right), 413.70$ $\left(\mathrm{Cd}^{2+}\right), 422.7\left(\mathrm{Ca}^{2+}\right), 2279.5\left(\mathrm{Mn}^{2+}\right)$ and $285.2\left(\mathrm{Mg}^{2+}\right)$.

X-ray diffraction studies were performed at 200 K using a Bruker Kappa Apex II diffractometer with monochromated Mo K $\alpha$ radiation $(\lambda=0.71073 \AA$ ). The crystal structures were solved by direct methods using SHELXTL [5] and refined with SHELXL [6]. Carbonbound hydrogen atoms were placed in calculated positions and refined riding. The water hydrogen atoms were located on the difference map and refined riding with the bond angles and lengths restrained. The nitrogen-bound hydrogens were located on the difference map and allowed to refine freely. All non-hydrogen atoms were refined anisotropically. Diagrams and publication material were generated using PLATON [7], and ORTEP-3 [8]. The protonation and formation constants were determined by potentiometric acid-base titrations in $10 \%$ ethanol in water using the Metrohm 794 Titrino equipped with a Metrohm LL Ecotrode. This method has been presented by us previously [9], but the only difference is the use of 0.10 M sodium perchlorate as the ionic medium. The concentration stability constants ( $\beta_{\mathrm{pqr}}$ ) were calculated using the computer program HYPERQUAD [10]. The pH measurements for extraction studies were performed on a Metrohm 827 pH meter using a combination electrode with 3 M KCl as an electrolyte. The Labcon microprocessorcontrolled orbital platform shaker model SPO-MP 15 was used for contacting the two phases of extraction. The melting points of the solid complexes were determined with the electrothermal IA 9000 digital measuring point apparatus.

### 2.3. Experimental Section

### 2.3.1. Preparation of $2,2^{\prime}$-Biimidazole

The ligand 2,2'-biimidazole $\left(\mathrm{BIIMH}_{2}\right)$ was prepared according to a method reported in the literature [11]. Yield $=17 \%$. M.p. $=348-350^{\circ} \mathrm{C}$. Anal. Calcd for $\mathrm{C}_{8} \mathrm{H}_{6} \mathrm{~N}_{3}$ (\%): C, 53.72; $\mathrm{H}, 4.51 ; \mathrm{N}, 41.77$. Found: C, 53.67; H, 4.70; N, 41.32. ${ }^{1} \mathrm{H}$ NMR $\left(\mathrm{CDCl}_{3}\right) \delta(\mathrm{ppm}): 7.13(4 \mathrm{H}, \mathrm{s}$, CH). IR ( $\left.v \max / \mathrm{cm}^{-1}\right)$ : 1693, $v(\mathrm{C}=\mathrm{Nim})$; 3327, $v(\mathrm{~N}-\mathrm{H})$.

### 2.3.2. Preparation of $2,2^{\prime}$-Alkylbiimidazoles

The alkylated derivatives of $\mathrm{BIIMH}_{2}$ (extractants) were also prepared according to a method found in the literature [12].

## 1-Heptyl-2,2'-Biimidazole (HBIIMH)

Yield $=51 \%$. Anal. Calcd for $\mathrm{C}_{8} \mathrm{H}_{6} \mathrm{~N}_{3}$ (\%): C, 67.21; H, 8.68; N, 24.12. Found: C, 67.33; $\mathrm{H}, 8.58 ; \mathrm{N}, 23.84 .{ }^{1} \mathrm{H}$ NMR ( $400 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ) $\delta(\mathrm{ppm}): \delta 7.30(2 \mathrm{H}, \mathrm{s}, \mathrm{CH}), 7.01(2 \mathrm{H}, \mathrm{s}, \mathrm{CH})$, $4.39\left(2 \mathrm{H}, \mathrm{m}, \mathrm{CH}_{2}\right), 1.69\left(2 \mathrm{H}, \mathrm{m}, \mathrm{CH}_{2}\right), 1.16\left(6 \mathrm{H}, \mathrm{m}, \mathrm{CH}_{2}\right), 0.81\left(3 \mathrm{H}, \mathrm{t}, \mathrm{CH}_{3}\right)$. IR $\left(v_{\max } / \mathrm{cm}^{-1}\right)$ : 1691, $v\left(\mathrm{C}=\mathrm{N}_{\mathrm{im}}\right)$; 3227, $v(\mathrm{~N}-\mathrm{H})$.
1-Octyl-2,2'-Biimidazole (OBIIMH)
Yield $=49 \%$. Anal. Calcd for $\mathrm{C}_{8} \mathrm{H}_{6} \mathrm{~N}_{3}$ (\%): C, 68.26; H, 9.00; N, 22.74. Found: C, 68.30; $\mathrm{H}, 8.89$; N, 21.99. ${ }^{1} \mathrm{H}$ NMR ( $400 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ) $\delta(\mathrm{ppm}): \delta 7.24(2 \mathrm{H}, \mathrm{s}, \mathrm{CH}), 6.99(2 \mathrm{H}, \mathrm{s}, \mathrm{CH})$, $4.39\left(2 \mathrm{H}, \mathrm{m}, \mathrm{CH}_{2}\right), 1.59\left(2 \mathrm{H}, \mathrm{m}, \mathrm{CH}_{2}\right), 1.14\left(6 \mathrm{H}, \mathrm{m}, \mathrm{CH}_{2}\right), 0.80\left(3 \mathrm{H}, \mathrm{t}, \mathrm{CH}_{3}\right)$. IR $\left(\mathrm{v}_{\max } / \mathrm{cm}^{-1}\right)$ : 1695, $v\left(\mathrm{C}=\mathrm{N}_{\mathrm{im}}\right) ; 3235, v(\mathrm{~N}-\mathrm{H})$.

## 1-Decyl-2,2'-Biimidazole (DBIIMH)

Yield $=45 \%$. Anal. Calcd for $\mathrm{C}_{8} \mathrm{H}_{6} \mathrm{~N}_{3}$ (\%): C, 70.03; H, 9.55; N, 20.42. Found: C, 70.08; $\mathrm{H}, 9.35 ; \mathrm{N}, 19.95 .{ }^{1} \mathrm{H}$ NMR ( $400 \mathrm{MHz}, \mathrm{CDCl}_{3}$ ) $\delta(\mathrm{ppm}): \delta 7.59(2 \mathrm{H}, \mathrm{s}, \mathrm{CH}), 7.00(2 \mathrm{H}, \mathrm{s}, \mathrm{CH})$, $4.39\left(2 \mathrm{H}, \mathrm{m}, \mathrm{CH}_{2}\right), 1.58\left(2 \mathrm{H}, \mathrm{m}, \mathrm{CH}_{2}\right), 1.20\left(6 \mathrm{H}, \mathrm{m}, \mathrm{CH}_{2}\right), 0.82\left(3 \mathrm{H}, \mathrm{t}, \mathrm{CH}_{3}\right)$. IR $\left(\mathrm{v}_{\max } / \mathrm{cm}^{-1}\right)$ : 1699, $v\left(\mathrm{C}=\mathrm{N}_{\mathrm{im}}\right)$; 3233, $v(\mathrm{~N}-\mathrm{H})$.
1,1'-Bis-heptyl-2,2'-biimidazole $\left(\mathrm{H}_{2} \mathrm{BIIM}\right)$
Yield $=50 \%$. Anal. Calcd for $\mathrm{C}_{8} \mathrm{H}_{6} \mathrm{~N}_{3}$ (\%): C, 72.68; $\mathrm{H}, 10.37 ; \mathrm{N}, 16.95$. IR $\left(v_{\max } / \mathrm{cm}^{-1}\right)$ : 1699, $v\left(\mathrm{C}=\mathrm{N}_{\mathrm{im}}\right)$; 3333, $v(\mathrm{~N}-\mathrm{H})$.

### 2.3.3. Extraction Method

All the solvent-extraction experiments were carried out in a temperature-controlled laboratory at $25( \pm 1)^{\circ} \mathrm{C}$. Equal volumes ( 5 mL ) of 0.001 M metal ion solution (aqueous layer) and organic layer (contains the extractant, 2-octanol, shellsol 2325 and DNNDSA) were pipetted into 50 mL conical separating funnels. They were shaken with an automated orbital platform shaker for 30 min at an optimized speed of 200 rpm . A minimum period of 24 h was observed before harvesting the raffinates. The raffinates were filtered through a 33 mm millex-HV Millipore of $0.45 \mu \mathrm{~m}$ and diluted appropriately for analysis by AAS. The percentage extractions $(\% \mathrm{E})$ of the metal ions were calculated from the concentrations of the metal ions in the aqueous phase using the equation below:

$$
\begin{equation*}
\% \mathrm{E}=\left(\frac{\mathrm{Ci}-\mathrm{Cs}}{\mathrm{Ci}}\right) \times 100 \tag{1}
\end{equation*}
$$

where Ci is the initial solution concentration ( $\mathrm{mg} / \mathrm{L}$ ) and Cs is the solution concentration after extraction. The extraction efficiencies were investigated as a function of pH , and all the extraction curves were plotted with the SigmaPlot 11.0 program.

### 2.3.4. Syntheses of Metal Complexes <br> Sulfonate Salts

The metal sulfonate salts were prepared by mixing 1:1 equimolar solution of toluene-4-sulfonic acid $\left(\mathrm{RSO}_{3} \mathrm{H}\right)$ with potassium hydroxide in absolute ethanol to produce the potassium toluene-4-sulfonate salt. The potassium toluene-4-sulfonate salt was added to $\mathrm{M}\left(\mathrm{ClO}_{4}\right)_{2} \cdot 6 \mathrm{H}_{2} \mathrm{O}\left(\mathrm{M}=\mathrm{Ni}^{2+}, \mathrm{Co}^{2+}, \mathrm{Cu}^{2+}\right.$ and $\left.\mathrm{Zn}^{2+}\right)$ in absolute ethanol. The potassium perchlorate salt was removed by centrifugation and filtered. The solution was concentrated and allowed to stand at room temperature to obtain the metal sulfonate salts.
$\mathrm{Ni}\left(\mathrm{RSO}_{3}\right)_{2} \cdot 6 \mathrm{H}_{2} \mathrm{O}$ : Color: light green. Yield $=77 \%$. M.p. $=244-246^{\circ} \mathrm{C}$. Anal. Calcd for $\mathrm{C}_{14} \mathrm{H}_{26} \mathrm{CoO}_{12} \mathrm{~S}_{2}$ (\%): C, 33.02; H, 5.15; S, 12.59. Found: C, 32.99; H, 5.01; S, 12.49. IR ( $\mathrm{cm}^{-1}$ ): 1000-1250, $\mathrm{v}_{3}\left(\mathrm{SO}_{3}\right)$.
$\mathrm{Co}\left(\mathrm{RSO}_{3}\right)_{2} \cdot 6 \mathrm{H}_{2} \mathrm{O}$ : Color: pale mauve. Yield $=76 \%$. M.p. $=243-245^{\circ} \mathrm{C}$. Anal. Calcd for $\mathrm{C}_{14} \mathrm{H}_{26} \mathrm{CoO}_{12} \mathrm{~S}_{2}(\%)$ : C, 33.01; H, 5.14; S, 12.59. Found: C, 32.94; H, 5.10; S, 12.53. IR ( $\mathrm{cm}^{-1}$ ): 1000-1250, $v_{3}\left(\mathrm{SO}_{3}\right)$.

## Preparation of Sulfonate Complexes

The preparation of coordination complexes, $\left[\mathrm{M}(\mathrm{BIIM})_{2}\left(\mathrm{RSO}_{3}\right)_{2}\right]$, was conducted in absolute ethanol under inert conditions. Hot ethanol solution ( 5 mL at $60^{\circ} \mathrm{C}$ ) containing 5 mmol of the ligand was added dropwise to 5 mL of the metal ion solution ( 1 mmol ) of each metal ion. Toluene sulfonic acid $\left(\mathrm{RSO}_{3} \mathrm{H}\right)(4 \mathrm{mmol})$ was added to dissolve the ligand. The mixture was heated at reflux overnight and precipitates were obtained, and these were filtered and washed with cold ethanol. A single crystal in the complex $\left[\mathrm{Cu}(\mathrm{BIIM})_{2}\left(\mathrm{RSO}_{3}\right)_{2}\right]$ was obtained by slow diffusion of diethyl ether into the mother liquor in a desiccator at room temperature for about one month.

## 3. Results and Discussion

### 3.1. Synthesis and Characterization of $2,2^{\prime}$-Biimidazole and Extractants

The synthesis of $2,2^{\prime}$-biimidazole involves cyclization via a condensation reaction, and the alkylation of the ligand was achieved by a nucleophilic attack of alkylbromide by anionic imidazole to obtain the extractant. The purity of the products was investigated by microanalysis and confirmed by ${ }^{1} \mathrm{H}$ NMR.

The ${ }^{1} \mathrm{H}$ NMR spectrum of $\mathrm{BIIMH}_{2}$ showed a peak at 7.13 ppm which was due to the four imidazole protons. The protons are chemically equivalent due to the $C_{2}$ symmetry of this compound. All ${ }^{1} \mathrm{H}$ NMR spectra of the ligand and extractants are provided in the Supplementary Materials (Figures S1-S6). The mono- and bis-alkylated biimidazole were successfully synthesized, and the appearance of the protons of the alkylated biimidazole at 7.01 and 7.30 ppm are in agreement with values found in the literature [11]. The appearance of peaks in the region of 0.070 to 4.5 ppm shows evidence of the connection of the alkyl chain to the imidazole nitrogen(s).

### 3.2. Solvent Extraction Studies

The extraction studies were carried out in a sulfate medium to define the optimal conditions for nickel(II) specificity. The conditions for the extraction of nickel(II) ions were optimized by investigating the essential concentration of the extractant, the concentration of the synergist (DNNDSA), the necessary alkyl chain substituent on imidazole and the effect of pH . Extractions required excess DNNDSA relative to quantities of dinonylnaphthalene sulfonic acid (DNNSA) used previously [3].

Figure S7 shows the effect of various mole ratios of Ni:OBIMH (1:25 to 1:40) on nickel(II) extraction. From these curves and the consequent data in Table S1, the ratio 1:30 showed a better extraction in terms of the steepness of the curve, i.e., a left-shifted curve and a slightly higher percentage extraction. For this reason, this metal to extractant molar ratio was chosen for the subsequent studies.

The involvement of DNNDSA as a synergist has been proven to be essential to this extraction method since there was a lack of extraction in its absence (Figure S8). This
could be rationalized on the basis that the sulfate ions do not readily phase-transfer the cationic complexes formed in the extraction system from the aqueous to the organic layer. This is due to the high hydration energies offered by the sulfate ions [13]. Therefore, the application of DNNDSA, which is a bulky organic acid with very low $\mathrm{p} K_{\mathrm{a}}$ values, eliminates the drawback posed by the sulfate ions. The role of the synergist (DNNDSA) is known to be that of an ion-pairing agent for the cationic metal ion complexes; therefore, the concentration of DNNDSA was investigated. Table S2 shows the extraction percentage as a function of pH . Initially low concentrations of DNNDSA were employed but this yielded low extraction efficiencies (Figure S9). The high concentrations resulted in significant extraction to the effect that 0.5 M was taken as optimal not because there was no further increase in \%E with an increase in DNNDSA concentration but because the concentration used was already very high in comparison to the DNNSA used previously [3]. The use of such a high concentration could be expected to have negative effects on the selective extraction of $\mathrm{Ni}^{2+}$ ions.

DNNDSA can be expected to behave similarly to DNNSA in terms of its extraction behavior. In view of this, it is not expected to show any selectivity between metal ions, as was shown for DNNSA [3]. The DNNSA-only extractions do not show a separation of the extraction curves of the base metals' ions as a function of pH (Table S3). This necessitates the use of a ligand that has been carefully designed to cause separation between the metal ions by exploiting the bonding preferences concerning coordination numbers, stereochemistry and type of bonding involved. Du Preez has coined the term stereochemical "tailor-making" to describe this effect [1]. This effect has been demonstrated in the separation of nickel and cobalt despite their similar coordination chemistry [14].

The optimized conditions for the concentration of the extractant (L) and co-extractant were a $1: 30 \mathrm{Ni}: L$ ratio for a 0.001 M nickel solution and 0.5 M for DNNDSA. The effect of the alkyl substituent on the extraction efficiencies is presented in Figure S10. It seems, from this investigation, that the octyl group gives the best extraction, as evidenced by higher percentage extraction (Table S4) and steepness of the curve. An investigation was also carried out to understand the effect of monoalkylated or bisalkylation on imidazole, and the monoalkylated OBIIMH showed better extraction compared with the bis-alkylated $\mathrm{O}_{2}$ BIIM (Figure S11, Table S5). The better performance (steeper curve) of OBIIMH was probably due to its less bulky nature, thus causing less entanglement of the alkyl chains with the neighboring imidazole.

The extraction patterns of the other metal ions typically present in a leach concentrate, including $\mathrm{Cu}^{2+}, \mathrm{Fe}^{2+}, \mathrm{Zn}^{2+}, \mathrm{Fe}^{3+}, \mathrm{Mn}^{2+}, \mathrm{Mg}^{2+}, \mathrm{Cd}^{2+}$ and $\mathrm{Ca}^{2+}$, were investigated under the conditions that were optimized for the extraction of nickel(II) ion (Figure 2, Table S6). There was no rejection of the hard ions $\left(\mathrm{Fe}^{3+}, \mathrm{Mn}^{2+}\right.$ and $\left.\mathrm{Ca}^{2+}\right)$ in the pH range under investigation, which does not coincide with the suggestion on the bonding nature of the aromatic nitrogenous ligands. The position of the copper extraction curve is rather surprising owing to the relatively higher acidic character of this metal ion, which should make it more reactive at the lower pH region. It is clear from the extraction pattern in Figure 2 that there is a lack of pH -metric separation of the metal ions, and the differences in $\%$ E may be influenced by the solubility of chelates formed which affect the distribution between the two phases.

In this solvent-extraction system, the protonation, complexation and phase distribution equilibria can be used to describe the system quantitatively with respect to the distribution ratio of a metal ion $\left(\mathrm{M}^{\mathrm{n}+}\right)$, and provide information on the coordination numbers involved in the extraction reaction [15]. The chelating agent (L) must distribute between the organic and aqueous phases to result in complexation in the aqueous phase, and that distribution coefficient is represented by $K_{D}(L)$ :

$$
\begin{equation*}
(\mathrm{L}) \mathrm{a} \rightleftharpoons(\mathrm{~L})_{\mathrm{o}} \text { and } K_{\mathrm{D}}(\mathrm{~L})=\frac{[\mathrm{L}] \mathrm{o}}{[\mathrm{~L}] \mathrm{a}} \tag{2}
\end{equation*}
$$

Figure 2. A plot of $\% \mathrm{E}$ vs. initial pH of equimolar concentration $(0.001 \mathrm{M})$ of $\mathrm{Ni}^{2+}, \mathrm{Co}^{2+}, \mathrm{Cu}^{2+}, \mathrm{Fe}^{2+}$, $\mathrm{Zn}^{2+}, \mathrm{Fe}^{3+}, \mathrm{Mn}^{2+}, \mathrm{Mg}^{2+}, \mathrm{Cd}^{2+}$ and $\mathrm{Ca}^{2+}$ extracted with OBIIMH (at M:L ratio of 1:30) and 0.5 M DNNSA in 80\% 2-octanol/Shellsol 2325 from dilute sulfate medium.

However, in the aqueous phase, the following two protonation equilibria may exist depending on the pH :

$$
\begin{gather*}
\mathrm{LH}_{2}^{2+} \rightleftharpoons \mathrm{H}^{+}+\mathrm{LH}^{+}, K_{a 1}=\frac{\left[\mathrm{H}^{+}\right]_{\mathrm{a}}\left[\mathrm{LH}^{+}\right]_{\mathrm{a}}}{\left[\mathrm{LH}_{2}^{2+}\right]_{\mathrm{a}}}  \tag{3}\\
\mathrm{LH}^{+} \rightleftharpoons \mathrm{H}^{+}+\mathrm{L}, \text { and } K_{a 2}=\frac{\left[\mathrm{H}^{+}\right]_{\mathrm{a}}[\mathrm{~L}]_{\mathrm{a}}}{\left[\mathrm{LH}^{+}\right]_{\mathrm{a}}} \tag{4}
\end{gather*}
$$

The metal ion chelates react with the neutral form of the ligand to form a cationic complex:

$$
\begin{equation*}
\mathrm{M}^{\mathrm{n}+}+\mathrm{mL} \rightleftharpoons \mathrm{ML}_{\mathrm{m}}{ }^{\mathrm{n}+} \text { and } K_{f}=\frac{\left[\mathrm{ML}_{\mathrm{m}}^{\mathrm{n}+}\right]_{\mathrm{a}}}{\left[\mathrm{M}^{\mathrm{n}+}\right]_{\mathrm{a}}[\mathrm{~L}]_{\mathrm{a}}^{\mathrm{m}}} \tag{5}
\end{equation*}
$$

The chelate which is ion-paired by an anion (in this case sulfonate anions represented by $\mathrm{X}^{\mathrm{n}-}$ ) to form an extractible species, $\left[\mathrm{ML}_{\mathrm{m}}\right] \mathrm{X}$, distributes itself between the organic and aqueous phases:

$$
\begin{equation*}
\left(\mathrm{ML}_{\mathrm{m}}^{\mathrm{n}+}\right)_{\mathrm{a}}+\left(\mathrm{X}^{\mathrm{n}-}\right)_{\mathrm{o} / \mathrm{a}} \rightleftharpoons\left(\mathrm{ML}_{\mathrm{m}} \mathrm{X}\right)_{\mathrm{o}}, \text { and } K_{\mathrm{D}}\left(\mathrm{ML}_{\mathrm{m}}^{\mathrm{n}+}\right)=\frac{\left[\mathrm{ML}_{\mathrm{m}} \mathrm{X}\right] \mathrm{o}}{\left[\mathrm{ML}_{\mathrm{m}}^{\mathrm{n}+}\right] \mathrm{a}} \tag{6}
\end{equation*}
$$

The distribution ratio (D), defined as the ratio of the concentration of the total metal species in the organic phase to that in the aqueous (regardless of its mode), is given by Equation (7), on the assumption that the metal chelate distributes largely in the organic phase and that the metal ion does not hydrolyse in the aqueous phase.

$$
\begin{equation*}
\mathrm{D} \approx \frac{\left[\mathrm{ML}_{\mathrm{m}} \mathrm{X}\right]_{\mathrm{o}}}{\left[\mathrm{M}^{\mathrm{n}+}\right]_{\mathrm{a}}} \tag{7}
\end{equation*}
$$

Substituting Equations (5) and (6), respectively, into Equation (7) yields Equation (8), depicting the formation constant and the concentration of the ligand in the aqueous phase as important parameters as well as the distribution coefficient of the chelate:

$$
\begin{equation*}
\mathrm{D}=K_{\mathrm{D}}\left(\mathrm{ML}_{\mathrm{m}}{ }^{\mathrm{n}+}\right) K_{f}[\mathrm{~L}]_{\mathrm{a}}^{\mathrm{m}} \tag{8}
\end{equation*}
$$

Equation (8) can be transformed to Equation (9) if Equation (2) is substituted, indicating that the concentration of L in the aqueous phase is dependent on its concentration in the organic phase and that its distribution between the two phases affects the distribution ratio of the complex formed:

$$
\begin{equation*}
\mathrm{D}=\frac{K_{\mathrm{D}}\left(\mathrm{ML}_{\mathrm{m}}{ }^{\mathrm{n}+}\right) K_{\mathrm{f}}}{K_{\mathrm{D}}(\mathrm{~L})^{\mathrm{m}}}[\mathrm{~L}]_{\mathrm{o}}^{\mathrm{m}} \tag{9}
\end{equation*}
$$

However, since the extractions are carried out at a low pH , it is necessary to consider the two protonation equilibria, respectively, because these species occur over a wide pH range, and competition of metal ions with protons for the ligand occurs early with pH due to the higher formation constants and the relatively low protonation constants (Section 3.3). Now, substituting Equations (3) and (4), respectively, into Equation (9) yields the following respective Equations (10) and (11):

$$
\begin{align*}
& \mathrm{D}=K_{\mathrm{D}}\left(\mathrm{ML}_{\mathrm{m}}^{\mathrm{n}+}\right) K_{f} K_{\mathrm{a} 2}{ }^{\mathrm{m}} \frac{\left[\mathrm{LH}^{+}\right]_{\mathrm{a}}^{\mathrm{m}}}{\left[\mathrm{H}^{+}\right]_{\mathrm{a}}^{\mathrm{m}}}  \tag{10}\\
& \text { and } \mathrm{D}=K_{\mathrm{D}}\left(\mathrm{ML}_{\mathrm{m}}^{\mathrm{n}+}\right) K_{f} K_{\mathrm{a} 2}{ }^{\mathrm{m}} K_{a 1} \mathrm{~m}^{\left[\mathrm{LH}_{2}^{2+}\right]_{\mathrm{a}}^{\mathrm{m}}}  \tag{11}\\
& {\left[\mathrm{H}^{+}\right]_{\mathrm{a}}^{2 \mathrm{~m}} }
\end{align*}
$$

Therefore, in the pH range where the monoprotonated species and a free ligand (Equation (4)) are involved, then a plot of $\log \mathrm{D}$ vs. pH (from taking the logarithms of both sides in Equation (10)) should yield a straight line with slope $m$ (number of ligands bonded to the metal ion $\mathrm{M}^{\mathrm{n}+}$ ). But in the highly acidic region where the second proton equilibrium (Equation (3)) is also active, then a plot of $\log \mathrm{D}$ vs. pH (from Equation (11)) should yield a straight line with slope 2 m . It is therefore not surprising that the slope of the plots is steeper in the lower pH range and flattens to about 2 as the pH increases (Figure 3). This accounts for the two-stage protonation, as a higher proportion of the ligand will be monoprotonated with an increase in pH . Therefore, bis coordination $(\mathrm{m} \approx 2)$ of $2,2^{\prime}$-biimidazole is supported by the extraction data.

### 3.3. Solution Complexation Studies

The ligand exhibits a two-stage protonation/deprotonation process and the highest $\log K_{\mathrm{a} 1}=5.96\left(\right.$ at $\left.25^{\circ} \mathrm{C}\right)$ and the lowest value correspond to the protonation/deprotonation of the second imidazole group $\left(\log K_{\mathrm{a} 2}=3.25\right.$ at $\left.25^{\circ} \mathrm{C}\right)$. Therefore, the loss of the first proton of the diprotonated species happens with ease and at a relatively low pH . The bidentate character in coordination was evidenced by the high formation constants that were calculated for the formation of the metal ion complexes with $\mathrm{BIIMH}_{2}$ (Table 1). The overall second stability constants are of the order $\mathrm{Cu}^{2+}(10.9)>\mathrm{Ni}^{2+}(10.7)>\mathrm{Zn}^{2+}(10.6)>$ $\mathrm{Co}^{2+}$ (10.3). This is not strictly the same order that was observed in the extraction curves at least for $\mathrm{Ni}^{2+}$ and $\mathrm{Cu}^{2+}$ (Figure 4), but these measure values are within the range of experimental error from one another. Nonetheless, this result shows that there is no relative stability preference between $\mathrm{BIIMH}_{2}$ and the base metal ions. Therefore, this extraction system is possibly governed by similar thermodynamics of complexation and results in a lack of pH -metric separation of the metal ions.

Figure 3. A plot of $\log \mathrm{D}$ vs equilibrium $\mathrm{pH}\left(\mathrm{pH}_{\mathrm{e}}\right)$ for the extraction of $0.001 \mathrm{M} \mathrm{M}^{2+}\left(\mathrm{M}=\mathrm{Mg}^{2+}, \mathrm{Zn}^{2+}\right.$, $\mathrm{Mn}^{2+}, \mathrm{Fe}^{2+}, \mathrm{Ni}^{2+}, \mathrm{Co}^{2+}$ and $\mathrm{Cu}^{2+}$ ) with OBIIMH (at M:L ratio of 1:30) and 0.5 M DNNSA in $80 \%$ 2-octanol/Shellsol 2325 from dilute sulfate medium.

$\mathrm{p}, \mathrm{q}$ and r refer to the coefficients of the species in the order of metal, ligand and proton. $\#=$ constant could not be calculated from current potentiometric data.

### 3.4. Synthesis and Characterization of Metal Complexes

A solution of toluene-4-sulfonic acid $\left(\mathrm{RSO}_{3} \mathrm{H}\right)(10 \mathrm{mmol})$ was mixed with an equimolar amount of potassium hydroxide ( 10 mmol ) in absolute ethanol to produce toluene-4sulfonate salt, which was filtered and left to dry at room temperature.

$$
\begin{align*}
& \mathrm{RSO}_{3} \mathrm{H}+\mathrm{KOH} \rightleftharpoons \mathrm{~K}^{+} \mathrm{RSO}_{3}^{-}+\mathrm{H}_{2} \mathrm{O}(\mathrm{R}=\text { toluene })  \tag{12}\\
& 2 \mathrm{~K}^{+} \mathrm{RSO}_{3}{ }^{-}+\mathrm{M}\left(\mathrm{ClO}_{4}\right)_{2} \rightleftharpoons \mathrm{M}\left(\mathrm{RSO}_{3}\right)_{2}+2 \mathrm{KClO}_{4}(\mathrm{~s}) \tag{13}
\end{align*}
$$

The metal sulfonates were formed from metal perchlorates, and the resulting potassium perchlorate was filtered out of solution before concentrating the metal sulfonates. Microanalaysis data supported the formation of the hexahydrate compounds $\mathrm{M}\left(\mathrm{RSO}_{3}\right)_{2} \cdot 6 \mathrm{H}_{2} \mathrm{O}$. The sulfonate salts were then used to synthesize the $2,2^{\prime}$-biimidazole complexes, and these were chareacterized by melting point, FTIR, electronic spectroscopy and single crystal X-ray crystallography. The melting points for both the metal sulfonate salts and complexes are surprisingly similar ( $243-248^{\circ} \mathrm{C}$ ).

### 3.4.1. Spectroscopic Characterization

The characteristic $v(N-H)$ frequencies as well as the $v(C=N)$ were found in the ranges $3311-3343 \mathrm{~cm}^{-1}$ and $1427-1448 \mathrm{~cm}^{-1}$, respectively, signifying the presence of coordinated imidazole in the complexes [16]. The presence of the sulfonate group is indicated by the $v\left(\mathrm{SO}_{3}\right)$ in the range $1321-1343 \mathrm{~cm}^{-1}$.

The electronic spectrum of the nickel(II) complex showed three d-d transitions at 350-400 nm, 510-650 nm and 820-1180 nm, respectively (Figure S12). These were assigned to the ${ }^{3} \mathrm{~T}_{1 \mathrm{~g}}(\mathrm{P}) \leftarrow{ }^{3} \mathrm{~A}_{2 \mathrm{~g}}(\mathrm{~F}),{ }^{3} \mathrm{~T}_{1 \mathrm{~g}}(\mathrm{~F}) \leftarrow{ }^{3} \mathrm{~A}_{2 \mathrm{~g}}(\mathrm{~F})$ and ${ }^{3} \mathrm{~T}_{2 \mathrm{~g}}(\mathrm{~F}) \leftarrow{ }^{3} \mathrm{~A}_{2 \mathrm{~g}}(\mathrm{~F})$ transitions, which are typical of an octahedral nickel(II) complex [17]. For the Co(II) complex, bands were observed at $350-385 \mathrm{~nm}, 420-580 \mathrm{~nm}$ and $1000-1400 \mathrm{~nm}$, which may be ascribed to ${ }^{4} \mathrm{~T}_{1 \mathrm{~g}}(\mathrm{P}) \leftarrow{ }^{4} \mathrm{~T}_{1 \mathrm{~g}}(\mathrm{~F}),{ }^{4} \mathrm{~A}_{2 \mathrm{~g}}(\mathrm{~F}) \leftarrow{ }^{4} \mathrm{~T}_{1 \mathrm{~g}}(\mathrm{~F})$ and ${ }^{4} \mathrm{~T}_{2 \mathrm{~g}}(\mathrm{~F}) \leftarrow{ }^{4} \mathrm{~T}_{1 \mathrm{~g}}(\mathrm{~F})$, respectively, for octahedral symmetry [18]. The electronic spectrum of the $\mathrm{Cu}(\mathrm{II})$ complex showed two bands at $360-560 \mathrm{~nm}$ and 590-1000 nm. In the $\mathrm{D}_{4 \mathrm{~h}}$ symmetry, the ${ }^{2} \mathrm{~T}_{2 \mathrm{~g}}$ level in octahedral geometry splits into ${ }^{2} \mathrm{E}_{\mathrm{g}}+{ }^{2} \mathrm{~B}_{2 g}$, while the higher ${ }^{2} \mathrm{E}_{\mathrm{g}}$ level is unaffected. The transitions are expected to correspond to ${ }^{2} \mathrm{~B}_{2 \mathrm{~g}} \leftarrow{ }^{2} \mathrm{E}_{\mathrm{g}}$ and ${ }^{2} \mathrm{E}_{\mathrm{g}} \leftarrow{ }^{2} \mathrm{E}_{\mathrm{g}}$ levels, respectively, for a distorted octahedral $\mathrm{Cu}(\mathrm{II})$ complex [19].

### 3.4.2. X-ray Crystallography

The ORTEP diagrams of $\mathrm{Co}\left(\mathrm{RSO}_{3}\right)_{2} \cdot 6 \mathrm{H}_{2} \mathrm{O}$ and $\left[\mathrm{Cu}\left(\mathrm{BIIMH}_{2}\right)_{2}\left(\mathrm{RSO}_{3}\right)_{2}\right]$ are illustrated in Figures 4-6, respectively. Selected crystallographic data are presented in Table 2, and selected bond lengths and angles are in Table 3. It appeared that there were traces of twinning in $\mathrm{Co}\left(\mathrm{RSO}_{3}\right)_{2} \cdot 6 \mathrm{H}_{2} \mathrm{O}(<2 \%)$ but attempts to take the twinning into account were unsuccessful. The CCDC deposition numbers are CCDC 2210845 and 2210846, respectively. The hexa-aqua $\mathrm{Co}(\mathrm{II})$ complex in the $\mathrm{Co}\left(\mathrm{RSO}_{3}\right)_{2} \cdot 6 \mathrm{H}_{2} \mathrm{O}$ structure is centrosymmetric, with extensive hydrogen interactions between the coordinated water molecules and the sulfonate groups (Figure 4). These interactions link adjacent complexes in a 2D network parallel to
the $a b(001)$ plane (Figure S13) and are presented in Table 4. The ring interactions are also presented in Table 5 and exhibit infinite stacked interactions parallel to the $a$ axis. There is a slight shortening of the bonds of the axial ligands ( $\mathrm{Co}-\mathrm{O} 21=2.046(4)) \AA$ in the hexa-aqua complex, while the equatorial bonds have lengths of 2.075(4) $\AA$ (Figure 5), and this is perhaps due to strong supramolecular interactions that are experienced in tosylate complexes [20-22].

Figure 5. ORTEP diagram of $\mathrm{Co}\left(\mathrm{RSO}_{3}\right)_{2} \cdot 6 \mathrm{H}_{2} \mathrm{O}$ showing an atom numbering scheme.

Figure 6. ORTEP diagram of $\left[\mathrm{Cu}(\mathrm{BIIM})_{2}\left(\mathrm{RSO}_{3}\right)_{2}\right]$ with ellipsoids drawn at $50 \%$ probability. Symmetry element: (i) 1-x, 1-y, 1-z.

Table 2. Selected crystallographic data for $\mathrm{Co}\left(\mathrm{RSO}_{3}\right)_{2} \cdot 6 \mathrm{H}_{2} \mathrm{O}$ and $\left[\mathrm{Cu}(\mathrm{BIIM})_{2}\left(\mathrm{RSO}_{3}\right)_{2}\right.$.

$\left[\mathrm{Cu}\left(\mathrm{BIIMH}_{2}\right)_{2}\left(\mathrm{RSO}_{3}\right)_{2}\right]$ is centrosymmetric, with the central copper(II) atom surrounded by two $\mathrm{BIIMH}_{2}$ ligands and two oxygen atoms of the sulfonate anions (Figure 6). The geometry of the complex is distorted octahedral, with the equatorial plane formed by the four imidazole nitrogen atoms, while oxygen atoms of the sulfonate anions occupy the apical positions. The equatorial distances for the copper complex are Cu1-N11 and $\mathrm{Cu}-\mathrm{N} 11^{\prime}=2.020(1) \AA$ and $\mathrm{Cu} 1-\mathrm{N} 13$ and $\mathrm{Cu} 1-\mathrm{N} 13^{\prime}=2.0202(1) \AA$, while the axial $\mathrm{Cu} 1-\mathrm{O} 21$ and $\mathrm{Cu} 1-\mathrm{O} 21^{\prime}$ distance is $2.430(1) \AA$. This is typical of a Jahn-Teller distorted copper(II) complex [15]. The majority of $\mathrm{Cu}(\mathrm{II})$ complexes are tetragonally distorted. The $\mathrm{Cu}-\mathrm{N}$ and $\mathrm{Cu}-\mathrm{O}$ bond lengths fall in the range normally observed for distorted octahedral copper(II) compounds $[15,16,23]$. The solid-state structure is in support of the observation of bis coordination observed in the extraction and in solution studies, as has been noticed previously [24], but this phenomenon is not always correlated due to differences in energetics of the solution vs. solid-state structures [25]. The solution/extraction studies and the electronic spectroscopic study, which suggested distorted octahedral complexes form with base metals, allowed us to conclude that the complexes are probably isostructural.

The two uncoordinated pyrrole-type nitrogens of the $\mathrm{BIIMH}_{2}$ ligands both have hydrogen interactions (Table 6) with a neighboring sulfonate ligand linking adjacent complexes in an infinite 2D network parallel to the $b c\left(\begin{array}{lll}1 & 0 & 0\end{array}\right)$ plane (Figure S14). This structure also exhibits extensive ring interactions with the shortest centroid-to-centroid distance of 3.8561(9) A (Table 7) between BIIMH2 ligands forming an infinite 2D network parallel to the $b c$ (10 0) plane.

## 4. Conclusions

A bidentate $N, N^{\prime}$-donor imidazole-based ligand, 2,2'-biimidazole $\left(\mathrm{BIIMH}_{2}\right)$, was applied as an extractant for extraction of base metal ions in an acidic sulfate medium. 1-Octyl-2-(2'-biimidazole) (OBIIMH), as a representative extractant, was applied in a solvent system, with dinonylnaphthalene disulfonic acid (DNNDSA) as a synergist. This study has established empirical evidence for the lack of separation of base metals in this system. Authors investigated the underlying chemistry and the findings from this study supported the lack of stereochemical "tailor-making" as a reason for the lack of pH -metric separation of base metals. It appears that the base metal complexes formed are isostructural with bis coordination of the bidentate ligand and inner sphere coordination of the sulfonate ions, and the complex formation constants are also similar, suggesting similar energetics of complexation. Of particular note is the non-innocent nature of bonding of the sulfonate ion instead of ion-pairing to form outer-sphere complexes.

#### Abstract

In the present work, novel polymeric copper(II) coordination compounds, namely [ $\mathrm{Cu}_{2}$ (cpida) $\left.\left(\mathrm{H}_{2} \mathrm{O}\right)_{4}\right][\mathrm{Cu}$ (cpida) $] \cdot 3 \mathrm{H}_{2} \mathrm{O}(\mathbf{1})$ (cpida ${ }^{3-}=2$-(carboxyphenyl)iminodiacetate anion) and $\mathrm{Na}[\mathrm{Cu}$ (cpida) $]$ (3), were synthesized and characterized using infrared spectroscopy, thermogravimetric analysis, elemental analysis, and single-crystal X-ray diffraction. Compound 1 was obtained by slowly evaporating an aqueous solution of $\mathrm{H}_{3}$ cpida, copper(II) sulfate, and NaOH at room temperature. The structural characterization revealed that $\mathbf{1}$ is an ionic entity formed by the $\left[\mathrm{Cu}(c \text { cpida) }]^{-}\right.$anion and the $\left[\mathrm{Cu}_{2} \text { (cpida) }\left(\mathrm{H}_{2} \mathrm{O}\right)_{4}\right]^{+}$cation, both of polymeric 1D structure. Compound 3 was prepared under similar conditions from copper perchlorate and crystallized via acetone diffusion. It is a coordination polymer formed by the $[\mathrm{Cu}(\mathrm{cpida})]^{-}$units, and the sodium cation is present in the structure, counterbalancing the anion charge. Depending on the crystallization conditions, it was possible to obtain other solvation forms of these structures. Starting from the conditions of compound 1, via the diffusion of ethanol, $\left[\mathrm{Cu}_{2}(\right.$ cpida $\left.)\left(\mathrm{H}_{2} \mathrm{O}\right)_{4}\right][\mathrm{Cu}($ cpida $)] \cdot \mathrm{H}_{2} \mathrm{O} \cdot 1 / 2 \mathrm{EtOH}(2)$ was precipitated, while a hydrate form of compound 3 with the formula $\mathrm{Na}[\mathrm{Cu}$ (cpida) $] \cdot 2 \mathrm{H}_{2} \mathrm{O}(4)$ was obtained via methanol diffusion.

Keywords: polynuclear complexes; X-ray crystal structures; $\mathrm{Cu}(\mathrm{II})$; 2-carboxyphenyliminodiacetic acid

## 1. Introduction

Over the past few decades, there has been substantial development in the research on polynuclear coordination compounds and coordination polymers, which is particularly fueled by their potential applications as materials for gas storage, catalysis, environmental remediation, drug delivery, and in magnetochemistry or semiochemistry [1-13].

According to the IUPAC recommendations, coordination polymers are "coordination compounds with repeating coordination entities extending in 1, 2, or 3 dimensions" [14,15]. In the structures of these compounds, there are inorganic nodes (metal-containing clusters or metal ions) connected by organic divergent molecules (called linkers or connectors) $[1,16,17]$. Rigid ligands with a high degree of directionality were originally used as linkers in order to obtain specific crystal motifs [18]. However, the employment of more flexible ligands in the development of coordination polymers has lately been explored by numerous research groups [19-33]. The flexibility arises from the rotation of single bonds in carbon chains [22], allowing for various conformations that can result in distinct final structures [24].

The employment of flexible ligands as linkers in coordination polymers has encountered some hurdles when compared with the use of less flexible or rigid connectors [24]. This is due to the fact that the process of self-assembling is dependent on the reaction conditions, particularly the solution pH value, the type of metal cation, the concentrations of the
different reactants, and the solvent employed. What is more, flexible polydentate ligands are also able to form mononuclear coordination compounds in competitive processes or adopt different conformations that are difficult to control.

Flexible molecules containing carboxylic acid groups are often chosen for the assembly of polynuclear coordination compounds. This preference is supported by the fact that this type of ligand can coordinate in different ways due to the possibility of fully or partially deprotonating the carboxylate groups, resulting in different topologies of the final structure [34]. These flexible molecules can act as bridging bidentate or tridentate ligands or chelating agents and even coordinate in a unidentate mode [35]. They are also good hydrogen bond acceptors capable of assembling supramolecular structures [36].

For several years now, we have focused our work on the development of polynuclear coordination compounds using polytopic flexible ligands. When working with aqueous solutions at mild acidic pH values, we reported the obtention of four capsule-like trinuclear copper(II) complexes assembled with nitrilotripropionic acid ( $\mathrm{H}_{3} \mathrm{ntp}$ ) $[37,38]$ and three new metal polynuclear compounds (containing nickel(II) or copper (II)) with Nbenzyliminodipropionic acid ( $\mathrm{H}_{2}$ bzlidp) [39]. In the case of the ntp complexes, the anion of copper salt had a significant influence on the obtained structure, defining the connectivity between the capsules [37]. When bzlidp ${ }^{2-}$ was employed as a ligand, it was possible to obtain $\mathrm{Cu}(\mathrm{II})$ complexes whose structures were significantly different (dinuclear complex vs. 2D layered structure) depending on the starting conditions [39].

We then turned our attention to the tricarboxylic acid compound 2-(carboxyphenyl) iminodiacetic acid ( $\mathrm{H}_{3}$ cpida, Figure 1) as a connector of the metal ions. This is a multidentate ligand with the ability to form five-membered chelate rings. It presents flexible iminodiacetate groups and an aromatic ring that can initiate $\pi-\pi$ interactions to stabilize the crystal packing.

Figure 1. Structure of 2-carboxyphenyliminodiacetic acid.
This ligand has already been employed in the preparation of mononuclear [40-43] and trinuclear coordination compounds [44] and high-nuclearity metal aggregates [45-49]. However, the employment of this tricarboxylic molecule to connect metal centers in a 1D structure has been scarcely studied [44,50,51]. Bandyopadhyay and collaborators reported two polymeric copper (II) compounds, $\left\{[\mathrm{Cu}(\mathrm{Hcpida})] \cdot \mathrm{H}_{2} \mathrm{O}\right\}_{\mathrm{n}}$ and $\left\{\left[\mathrm{Cu}(\mathrm{Hcpida})\left(\mathrm{H}_{2} \mathrm{O}\right)\right] \cdot \mathrm{H}_{2} \mathrm{O}\right\}_{\mathrm{n}}$ [50]. In the first compound, the copper centers are pentacoordinated, showing a square pyramid geometry with the Hcpida ${ }^{2-}$ anion bridging the metal ions through the carboxylate groups attached to the phenyl ring. In this complex, one of the carboxylate groups remains protonated, stabilizing the chains through hydrogen bonds. In the second compound, the Cu (II) center is hexacoordinated, presenting a distorted octahedral geometry. The protonated carboxylate group is connected to the coordinated water molecule of a $\left[\mathrm{Cu}(\mathrm{Hcpida})\left(\mathrm{H}_{2} \mathrm{O}\right)\right]$ unit of an adjacent chain through a hydrogen bond. In this way, cylindrical channels are formed in the structure that hosts the water crystallization molecule. Yong and coworkers described a Cd (II) coordination polymer, $\left[\mathrm{Cd}_{3}(\text { cpida })_{2}\left(\mathrm{H}_{2} \mathrm{O}\right)\right] \cdot \mathrm{H}_{2} \mathrm{O}$, which contains three crystallographically independent Cd (II) centers and forms infinite helical chains [51]. Heteroleptic $\mathrm{Cu}(\mathrm{II})$ chain-like structures can also be found in the literature. Ma and coworkers characterized a $\mathrm{Cu}($ II $)$ coordination polymer containing the cpida ${ }^{3-}$ anion and 1,10-phenantroline (phen) with a $\left\{\left[\mathrm{Cu}_{2} \text { (cpida)(phen) }\left(\mathrm{NO}_{3}\right)\right] \cdot 2 \mathrm{H}_{2} \mathrm{O}\right\}_{n}$ formula. The complex contains two five-coordinated copper(II) centers with a square pyramid geometry. Two cpida ${ }^{3-}$ anions bridge three copper
ions, forming a trinuclear triangular cluster that, in turn, is connected by their vertices, forming a 1D structure [44]. Polymeric coordination compounds based on the meta and para isomers of the 2-(carboxyphenyl)iminodiacetate anion have also been reported [35,52-54].

We decided to further explore the potential of $\mathrm{H}_{3}$ cpida to form polynuclear systems, in conditions analogous to those employed in the preparation of the $\mathrm{H}_{2}$ bzlidp or $\mathrm{H}_{3}$ ntp compounds mentioned above. Copper(II) was used as a metal ion and we report the preparation of four new copper(II) polynuclear compounds, $\left[\mathrm{Cu}_{2}(\right.$ cpida $\left.)\left(\mathrm{H}_{2} \mathrm{O}\right)_{4}\right][\mathrm{Cu}$ (cpida) $] \cdot 3 \mathrm{H}_{2} \mathrm{O}(\mathbf{1})$, $\left[\mathrm{Cu}_{2}\right.$ (cpida) $\left.\left(\mathrm{H}_{2} \mathrm{O}\right)_{4}\right][\mathrm{Cu}$ (cpida) $] \cdot \mathrm{H}_{2} \mathrm{O} \cdot 1 / 2 \mathrm{EtOH}(2), \mathrm{Na}[\mathrm{Cu}($ cpida $)]$ (3), and $\mathrm{Na}[\mathrm{Cu}($ cpida $)] \cdot 2 \mathrm{H}_{2} \mathrm{O}$ (4), obtained under different crystallization conditions.

## 2. Materials and Methods

### 2.1. General Information

All common laboratory chemicals were reagent grade, acquired from commercial suppliers, and employed without additional purification. Elemental analysis ( $\mathrm{C}, \mathrm{H}, \mathrm{N}, \mathrm{S}$ ) was carried out on a Flash 2000 instrument (Thermo Fisher Scientific, USA). The infrared spectra, as KBr pellets, were obtained on an FTIR Shimadzu IR-Prestige-21 spectrophotometer (Shimadzu, Kyoto, Japan) in the $4000-400 \mathrm{~cm}^{-1}$ range. Thermogravimetric analyses (TGAs) were executed in a Shimadzu TGA-50 instrument with a TA 501 interface (Shimadzu, Kyoto, Japan), using platinum cells. TGAs were recorded under a nitrogen stream ( $50 \mathrm{~mL} \mathrm{~min}{ }^{-1}$ ) at $1.0^{\circ} \mathrm{C} \mathrm{min}{ }^{-1}$ up to $300^{\circ} \mathrm{C}$ and $30^{\circ} \mathrm{C} \mathrm{min}{ }^{-1}$ from 300 to $700^{\circ} \mathrm{C}$.

CAUTION! Perchlorate salts of metal coordination compounds containing organic ligands have the potential to be explosive. Only small quantities of material should be prepared and it should be handled with caution.

### 2.2. Synthesis of the Complexes

### 2.2.1. Synthesis of $\left[\mathrm{Cu}_{2}\right.$ (cpida) $\left.\left(\mathrm{H}_{2} \mathrm{O}\right)_{4}\right][\mathrm{Cu}$ (cpida) $] \cdot 3 \mathrm{H}_{2} \mathrm{O}$ (1)

$\mathrm{H}_{3}$ cpida ( $0.167 \mathrm{~g}, 0.66 \mathrm{mmol}$ ) was dissolved in distilled water $(12 \mathrm{~mL})$ and copper sulfate ( $0.159 \mathrm{~g}, 1.00 \mathrm{mmol}$ ) was added. The solution was magnetically stirred at room temperature and adjusted to pH 4.1 with $5 \mathrm{~mol} \mathrm{~L}^{-1} \mathrm{NaOH}$ solution. The blue solution was filtered and the solvent was slowly evaporated at room temperature. After four months, 1 precipitated as green crystals. The crystals were filtered through paper and washed with cold distilled water $\left(0^{\circ} \mathrm{C}\right)$. The solid material was dried in open air, and 0.084 g of the product was obtained. The yield was $31 \%$ (based on copper(II)). Anal. Calc. for $\mathrm{C}_{22} \mathrm{H}_{30} \mathrm{Cu}_{3} \mathrm{~N}_{2} \mathrm{O}_{19} ; \mathrm{C}, 32.34 ; \mathrm{H}, 3.70 ; \mathrm{N}, 3.43$. Found: C, 31.90; H, 3.45; N 3.39\%. Selected IR data ( $v_{\max } / \mathrm{cm}^{-1}$ ): 3447, 3178, 2968 (sh), 2929 (sh), 1599, 1549, 1481, 1454, 1410, 1306, 1259, 1175, 1117, 1084, 1032, 1001, 990, 957, 932, 880, 812, 763, 723, 710, 646,594, 527, 446. TGA (30-700 ${ }^{\circ} \mathrm{C}, \mathrm{N}_{2}$ ), \% weight loss: 11.29 (left limit $19^{\circ} \mathrm{C}$-right limit $63{ }^{\circ} \mathrm{C}$ ), 4.95 (left limit $63{ }^{\circ} \mathrm{C}$-right limit $139^{\circ} \mathrm{C}$ ), 38.95 (left limit $170^{\circ} \mathrm{C}$-right limit $328^{\circ} \mathrm{C}$ ), $7.26 \%$ (left limit $328^{\circ} \mathrm{C}$-right limit $700^{\circ} \mathrm{C}$ ).

### 2.2.2. Synthesis of $\left[\mathrm{Cu}_{2}\right.$ (cpida) $\left.\left(\mathrm{H}_{2} \mathrm{O}\right)_{4}\right][\mathrm{Cu}($ cpida $)] \cdot \mathrm{H}_{2} \mathrm{O} \cdot 1 / 2 \mathrm{EtOH}$ (2)

$\mathrm{H}_{3}$ cpida ( $0.253 \mathrm{~g}, 1.0 \mathrm{mmol}$ ) was dissolved in distilled water $(6 \mathrm{~mL})$ and the pH was set to 7 through addition of $5 \mathrm{~mol}^{-1} \mathrm{NaOH}$. This solution was added to a 2 mL aqueous solution of copper trifluoromethanesulfonate ( $0.543 \mathrm{~g}, 1.5 \mathrm{mmol}$ ). The solution was stirred at room temperature and its pH adjusted to 5.2 with aqueous $5 \mathrm{~mol} \mathrm{~L}^{-1} \mathrm{NaOH}$ solution. This solution was subsequently divided into two portions of 4 mL each, which were set to crystalize either by diffusion of ethanol or methanol vapors. After 21 d , green crystals were obtained from the first (ethanol vapors). The crystals were filtered through paper and washed with cold distilled water $\left(0^{\circ} \mathrm{C}\right)$. After allowing the crystals to dry in open air, 0.070 g of 2 was obtained. The yield was $35 \%$ (based on copper(II)). Anal. Calc. for $\mathrm{C}_{46} \mathrm{H}_{58} \mathrm{Cu}_{6} \mathrm{~N}_{4} \mathrm{O}_{35}$ : C, 34.35; H, 3.64; N, 3.48. Found: C, 33.54; H, 3.61; N 3.34\%. Selected IR data ( $v_{\max } / \mathrm{cm}^{-1}$ ): 3447, 3145 (sh), 2972, 2928, 2855, 1609, 1564, 1547, 1479, 1454, 1408, 1373, $1304,1258,1173,1121,1086,1040,999,957,934,876,808,766,721,712,646,590,525$.

Blue needle-shaped crystals of a different compositions were obtained from the diffusion of methanol (see below).

### 2.2.3. Synthesis of $\mathrm{Na}[\mathrm{Cu}$ (cpida)] (3)

$\mathrm{H}_{3}$ cpida ( $0.253 \mathrm{~g}, 1.0 \mathrm{mmol}$ ) was dissolved in 6 mL of distilled water and the pH value of the resulting solution was set to 7 by adding $\mathrm{NaOH}\left(5 \mathrm{~mol} \mathrm{~L}^{-1}\right.$ solution). This ligand solution was added to a 2 mL aqueous solution of copper perchlorate hexahydrate ( 0.556 g , 1.5 mmol ). The solution was stirred at room temperature and its pH was set to 5.2 , again with $5 \mathrm{~mol} \mathrm{~L}^{-1} \mathrm{NaOH}$ solution. Blue needle-shaped crystals were obtained after 60 days, produced from 2 mL of this solution via diffusion of acetone vapors. These crystals were filtered, washed with cold distilled water $\left(0^{\circ} \mathrm{C}\right)$, and allowed to dry in open air. Following this procedure, 0.034 g of the product was obtained. The yield was $40 \%$ (based on $\mathrm{H}_{3}$ cpida). Anal. Calc. for $\mathrm{C}_{11} \mathrm{H}_{8} \mathrm{CuNNaO}_{6} ; \mathrm{C}, 39.24 ; \mathrm{H}, 2.39 ; \mathrm{N}, 4.16$. Found: \% C, 38.82; H, 2.42; N $4.06 \%$. Selected IR data $\left(\gamma_{\max } / \mathrm{cm}^{-1}\right): 3441,2979,2939,1674,1638,1616,1483,1450,1396$, $1385,1339,1219,1171,1152,1103,1061,1045,961,941,908,881,853,777,752,669,617,575$, 550, 523, 442.

### 2.2.4. Synthesis of $\mathrm{Na}[\mathrm{Cu}$ (cpida) $] \cdot 2 \mathrm{H}_{2} \mathrm{O}$ (4)

$\mathrm{H}_{3}$ cpida ( $0.253 \mathrm{~g}, 1.0 \mathrm{mmol}$ ) was dissolved in 6 mL of distilled water and the pH was set to 7 with the addition of $\mathrm{NaOH}\left(5 \mathrm{~mol} \mathrm{~L}^{-1}\right.$ solution), drop by drop. This solution was added to 2 mL of aqueous copper perchlorate hexahydrate solution ( $0.556 \mathrm{~g}, 1.5 \mathrm{mmol}$ ). The mixture was magnetically stirred at room temperature and the pH was set to 5.2 with aqueous NaOH solution. Blue needle-shaped crystals of compound 4 were obtained after 50 days, produced from 2 mL of the resulting solution via diffusion of methanol vapors. The crystals were separated by filtration, washed with cold water $\left(0^{\circ} \mathrm{C}\right)$, and dried in open air. Following this procedure, 0.035 g of the product was obtained. The yield was $38 \%$ (based on $\mathrm{H}_{3}$ cpida) Anal. Calc. for $\mathrm{C}_{11} \mathrm{H}_{12} \mathrm{CuNNaO}_{8}, \mathrm{C}, 35.44 ; \mathrm{H}, 3.25 ; \mathrm{N}, 3.76$. Found: C, $35.05 ; \mathrm{H}, 3.12 ; \mathrm{N}, 3.54 \%$. Selected IR data $\left(~_{\max } / \mathrm{cm}^{-1}\right): 3423,2970,2932,1657,1634,1481$, 1447, 1402, 1369, 1346, 1317, 1228, 1182, 1163, 1148, 1099, 1063, 1049, 982, 959, 941, 910, 880, $853,766,752,708,671,652,617,578,552,529,492,447$. TGA ( $30-700{ }^{\circ} \mathrm{C}, \mathrm{N}_{2}$ ) \% weight loss: 8.00 (left limit $19^{\circ} \mathrm{C}$-right limit $120^{\circ} \mathrm{C}$ ), 34.66 (left limit $100^{\circ} \mathrm{C}$-right limit $305^{\circ} \mathrm{C}$ ), 20.96 (left limit $305^{\circ} \mathrm{C}$-right limit $700^{\circ} \mathrm{C}$ ).

Compound 4 could also be obtained from copper trifluoromethanesulfonate, in a similar manner as compound 2 but using methanol for the diffusion $(0.0315 \mathrm{~g})$.

### 2.3. X-ray Crystallography

The X-ray diffraction data for all compounds were collected with a Rigaku SuperNOVA diffractometer with microfocus X-ray using $\mathrm{Cu} / \mathrm{Mo} \mathrm{K} \alpha$ radiation $(\lambda=1.54184 / 0.71073 \AA$ ). CrysAlisPro 1.171.39.46 [55] software was employed to collect, index, scale, and apply analytical absorption correction based on the faces of the crystal. The SHELXT program was used to solve the structure with a dual-space algorithm [56]. Fourier recycling and least-squares refinement were used for the model completion with SHELXL-2019 [57]. All non-hydrogen atoms were refined anisotropically, and all hydrogen atoms were placed in geometrically suitable positions and refined through riding with the isotropic thermal parameter related to the equivalent isotropic thermal parameter of the parent atom. The hydrogen atoms were geometrically positioned with C-H $=0.93 \AA$ and $\operatorname{Uiso}(\mathrm{H})=1.2 \mathrm{Ueq}(\mathrm{C})$. The geometrical analysis of interactions in the structure was performed with the Olex2 [58] program (version 1.5).

The crystal data, collection procedures, and refinements results are summarized in Table 1.

## 3. Results and Discussion

### 3.1. Synthesis of the Complexes

The coordination compounds were prepared by directly mixing aqueous solutions of the corresponding copper salts and $\mathrm{H}_{3}$ cpida, setting the pH value in the 4.0-5.2 range, and using a 1.5 copper-to-ligand ratio (Scheme 1 ).

Scheme 1. Synthesis of the complexes 1-4.

The crystals were characterized via infrared spectroscopy and elemental analysis. IR spectra of compounds 1,2 , and 4 exhibit a broad band in the $3200-3600 \mathrm{~cm}^{-1}$ region. The presence of this band is indicative of the existence of water molecules in the crystal structures. The small absorption peaks that appeared in the $3000-2850 \mathrm{~cm}^{-1}$ region for the four complexes correspond to the $v_{\mathrm{C}-\mathrm{H}}$ vibration modes of the $-\mathrm{CH}_{2}$ - groups in the alkyl chains on the cpida ${ }^{3-}$ anion (Figures S1-S4 Supplementary Material). The absence of the distinctive band of $v_{\mathrm{as}}(\mathrm{COOH})$ at $c a .1700 \mathrm{~cm}^{-1}$ indicates that the carboxylate groups of the ligand are fully deprotonated in these compounds. For complexes 1 and 2, the $v_{\mathrm{as}}\left(\mathrm{COO}^{-}\right)$vibrations appeared at ca. $1600 \mathrm{~cm}^{-1}$, whereas those of $v_{\mathrm{s}}\left(\mathrm{COO}^{-}\right)$occurred at ca. $1410 \mathrm{~cm}^{-1}$. In the case of compounds 3 and 4 , the bands around $1635 \mathrm{~cm}^{-1}$ can be assigned to the asymmetric stretching of the $\mathrm{COO}^{-}$of the complexes while those that appeared in the proximity of $1400 \mathrm{~cm}^{-1}$ correspond to $v_{\mathrm{s}}\left(\mathrm{COO}^{-}\right)$. In all cases, the elemental analysis is consistent with the proposed empirical formula.

The TGA curve for compound 1 (Figure S5, Supplementary Material) shows, below $140^{\circ} \mathrm{C}$, a dehydration process that occurs in two steps, with a weight loss of $16.2 \%$. The dehydration process is consistent with the loss of seven water molecules, comprising both lattice water molecules and coordinated ones. This is followed by a $46 \%$ weight loss step that involves the decomposition of the organic ligand. This is similar to what has previously been observed in the TG analysis of complexes containing the cpida ligand [43,44,50,51,53]. In the case of compound 4, the TGA curve (Figure S6, Supplementary Material) shows a weight loss of $8 \%$ below $120^{\circ} \mathrm{C}$, consistent with a two-molecule dehydration process, and a two-step decomposition process with a weight loss of circa $56 \%$, corresponding to the decomposition of the organic ligand. Single crystals for the complexes were obtained through slow evaporation of the solvent (1), and slow diffusion of ethanol (2), acetone (3), and methanol (4), at room temperature. Crystallographic data of compounds 1 to 4 are summarized in Table 1.

### 3.2. Crystal Structure of $\left[\mathrm{Cu}_{2}(c\right.$ pida $\left.)\left(\mathrm{H}_{2} \mathrm{O}\right)_{4}\right][\mathrm{Cu}(c$ cpida $)] \cdot 3 \mathrm{H}_{2} \mathrm{O}(\mathbf{1})$ and of [ [Cu $\mathrm{C}_{2}$ (cpida) $\left.\left(\mathrm{H}_{2} \mathrm{O}\right)_{4}\right][\mathrm{Cu}($ cpida $\left.)] \cdot \mathrm{H}_{2} \mathrm{O} \cdot 1 / 2 \mathrm{EtOH}\right]$ (2)

Compound $\mathbf{1}$ crystallizes in the monoclinic $\mathrm{P} 2_{1} / \mathrm{n}$ space group (Table 1 ). Selected bond lengths and angles for $\mathbf{1}$ are presented in Table 2 and in Table S1 (Supporting Information). The asymmetric unit of $\left[\mathrm{Cu}_{2}(\right.$ cpida $\left.)\left(\mathrm{H}_{2} \mathrm{O}\right)_{4}\right][\mathrm{Cu}($ cpida $)]$ is shown in Figure 2a. Compound 1 is a salt formed by the $[\mathrm{Cu} \text { (cpida) }]^{-}$anion and the $\left[\mathrm{Cu}_{2}(\text { cpida })\left(\mathrm{H}_{2} \mathrm{O}\right)_{4}\right]^{+}$cation, both of them being polymeric, in a type of structure that is quite common with this kind of iminocarboxylic ligand $[39,50]$. The structure also presents three lattice water molecules. The anion is formed by [Cu(cpida)] units, connected by carboxylate oxygen atoms. Each unit contains a $\mathrm{Cu}(\mathrm{II})$ ion coordinated to a cpida ${ }^{3-}$ anion, which acts as a tetradentate ligand. In order to assess the coordination geometry of Cu 2 , which shows five ligated atoms, the $\tau$ factor was determined. This is a geometrical parameter proposed by Addison and coworkers [59] to classify five coordinated structures in square pyramidal ( $\tau$ factor $=0$ ) or trigonal bipyramids ( $\tau$ factor $=1$ ). According to this parameter, the coordination polyhedron of the Cu 2 atom can be depicted as a slightly distorted square pyramid ( $\tau$ factor $=0.33$ ), the donor atoms being the nitrogen atom N2, and three oxygen atoms of each carboxylate of the cpida ${ }^{3-}$ anion (O8, O9, and O12, Figure 2b). The coordination sphere is completed by the O-carboxylate of a neighboring [Cu(cpida)] unit. Therefore, two of the carboxylate groups are coordinating in a monodentate mode, while the third is acting as bridging bidentate, in a syn-anti conformation and with a $\mathrm{Cu}-\mathrm{Cu}$ separation of $5.25(7) \AA \mathrm{Cu}(\mathrm{II})$ ida or substituted ida complexes have shown this kind of connection [44,60-62] as opposed to the one previously reported [50] where the bridging carboxylate group was the one attached to the phenyl ring.

Figure 2. (a) Asymmetric unit of the structure of compound 1 with labeling; (b) chain-like structure of the $\left[\mathrm{Cu}(\text { cpida) }]^{-}\right.$anion; (c) chain-like structure of the $\left[\mathrm{Cu}_{2}(\mathrm{cpida})\left(\mathrm{H}_{2} \mathrm{O}\right)_{4}\right]^{+}$cation; (d) 1D polymeric structure of compound 1 showing the arrangement of the adjacent chains. Thermal ellipsoids are shown at $50 \%$ probability. Hydrogen atoms are omitted for clarity. Color code: O (red), N (blue), carbon (grey), Cu (orange).

The $\left[\mathrm{Cu}_{2}(\text { cpida })\left(\mathrm{H}_{2} \mathrm{O}\right)_{4}\right]^{+}$cation is dinuclear and it is formed by $[\mathrm{Cu}($ cpida $)]$ units connected by carboxylate oxygen atoms. The coordination around Cu 1 is also a distorted square pyramid $(\tau$ factor $=0.278)$ [59], with the donor atoms being three oxygen atoms, one of each carboxylate of the cpida ${ }^{3-}$ ligand ( $\mathrm{O} 2, \mathrm{O} 3$, and O 6 ), and the nitrogen atom N 1 (Figure 2c). The fifth coordination position is occupied by the O 1 atom of a neighboring acetic group that is acting as a bridging bidentate group, in a syn-anti conformation and with a $\mathrm{Cu} 1-\mathrm{Cu} 1$ separation of 5.17 (7) $\AA$. In this way, a 1D chain of [Cu(cpida)] is formed, which is similar to the anionic chain in the structure. The cation presents a second Cu atom (Cu3), which is pentacoordinated, again with a very slightly distorted square pyramid ( $\tau$ factor $=0.002$ ) [59]. The donor atoms are the oxygen atoms of four water molecules (O1W, O2W, O3W, and O4W) and the O5 atom of a carboxylate group. This carboxylate group, which is directly attached to the phenyl ring, is bridging Cu 1 and Cu 3 in a syn-anti conformation. The equatorial positions of the square pyramid are occupied by the O 5 atom and three of the coordinated water molecules (O2W, O3W, and O4W), while the fourth water molecule (O1W) is placed at the axial position. The crystal packing is reinforced by hydrogen bonds between the lattice water molecules and the carboxylate oxygen atoms with an average donor acceptor distance of $d(\mathrm{D} \cdot \cdot \mathrm{A})=2.74(8) \AA$ and an average D-H $\cdot \mathrm{A}$ angle of $161.8^{\circ}$ (Table S3, Supporting Information).

Compound 2 was obtained under similar conditions as those used for compound 1, save for the copper source and diffusion vapors. Selected bond lengths and angles for compound 2 are showed in Table 2 and in Table S1 (Supporting Information). The compound crystallizes in the monoclinic $\mathrm{P} 2_{1} / \mathrm{n}$ space group (Table 1 ) and its structure is similar to that of compound $\mathbf{1}$, with the difference that just one lattice water molecule and half a molecule of ethanol are present per asymmetric unit (Figure 3a). Compound 2 is also composed of the $\left[\mathrm{Cu}_{2}(\text { cpida })\left(\mathrm{H}_{2} \mathrm{O}\right)_{4}\right]^{+}$cation and the $[\mathrm{Cu}(\text { cpida })]^{-}$anion, both presenting a chain-like structure. In the $\left[\mathrm{Cu}_{2}(\text { cpida })\left(\mathrm{H}_{2} \mathrm{O}\right)_{4}\right]^{+}$cation, the coordination polyhedron
around Cu 1 is also a distorted square pyramid $(\tau$ factor $=0.281$ ) [59], with the donor atoms being three oxygen atoms of each carboxylate group of the cpida ${ }^{3-}$ anion $(\mathrm{O} 2, \mathrm{O} 3$, and O6, Figure 3a) and the nitrogen atom N1. The fifth coordination position is occupied by the O1 atom of a neighboring acetic group, which is acting as a bridging bidentate group in a syn-anti conformation, and with a $\mathrm{Cu} 1-\mathrm{Cu} 1$ separation of $5.17(7) \AA$. The Cu atom (Cu3) is pentacoordinated, and again with a slightly distorted square pyramid geometry $(\tau$ factor $=0.01$ ) [59]. The donor atoms are the oxygen atoms of four water molecules (O1W, O2W, O3W, and O4W) and O5 of the carboxylate group attached to the phenyl ring. This carboxylate group is bridging Cu 1 and Cu 3 in a syn-anti conformation. Three water molecules (O1W, O2W, and O4W) and the O5 atom are occupying the equatorial positions of the square pyramid, while the fourth coordinated water molecule (O3W) is placed at the axial position.

In the $[\mathrm{Cu} \text { (cpida) }]^{-}$anion, the coordination geometry around the Cu 2 atom can be described as a slightly distorted square pyramid ( $\tau$ factor $=0.36$ ) [59], with the donor atoms being the nitrogen atom N2 and three oxygen atoms, one of each carboxylate group of the cpida ${ }^{3-}$ anion (O8, O9, and O12, Figure 3a). The coordination polyhedron is completed by the O-carboxylate of a neighboring [Cu(cpida)] unit. One of the acetic carboxylate groups is acting as a bridging bidentate, in a syn-anti conformation and with a $\mathrm{Cu}-\mathrm{Cu}$ separation of 5.25(7) A.

The crystal packing is reinforced by hydrogen bonds between the lattice water molecules, the ethanol molecules, and the carboxylate oxygen atoms, with an average donor acceptor distance of $d(\mathrm{D} \cdot \mathrm{A})=2.73(5) \AA$ and an average D-H. $\cdot$ A angle of $162.2^{\circ}$ (Table S4, Supporting Information). An unusual $\mathrm{C}(4)-\mathrm{H}(4 \mathrm{~B}) \cdot \mathrm{O}(13)^{\# 1}$ hydrogen bond between the ethanol $\mathrm{O}(13)$ atom and the $\mathrm{CH}_{2}$ group of the cationic chain is also present (Table S4).

Given that the unit cells of $\mathbf{1}$ and $\mathbf{2}$ showed practically the same geometrical parameters and the same symmetry, we performed an analysis to further characterize these similarities. Using the COMPSTRU feature available on the Bilbao Crystallographic Server (https: / /www.cryst.ehu.es/ accessed on 14 April 2023), we checked the relationship between both structures, after removing the corresponding solvent molecules. It was found that there is no pair of atoms transformable with a one-angstrom tolerance. Mercury's structure overlay tool (Mercury version 2022.3.0) [63] was also employed, with us observing that when increasing the number of pairs of atoms to overlap, the RMSD between the chosen molecules increased more and more.

### 3.3. Crystal structure of $\mathrm{Na}[\mathrm{Cu}($ cpida) $]$ (3)

Compound 3 crystallizes in an orthorhombic Pbca space group (Table 1). Selected bond lengths and angles for 3 can be found in Table 3 and Table S2 (Supporting Information). The asymmetric unit (Figure 4a) is composed of the $[\mathrm{Cu} \text { (cpida) }]^{-}$anion with the cpida ${ }^{3-}$ ligand coordinated to the Cu cation in a tridentate manner. The coordination sphere of the copper center is square planar, with the donor atoms being N1, O5, O3, and the O1 ${ }^{\# 5}$ atom of a neighboring [ Cu (cpida)] unit, with an average $\mathrm{Cu}-\mathrm{O}$ distance of 1.92(4) $\AA$ and a $\mathrm{Cu}-\mathrm{N}$ distance of $2.046(5) \AA$. The O1 atom is located in an axial position, at a longer Cu1-O1 distance. Therefore, the [Cu(cpida)] fragments form a chain-like structure, in a zig-zag motif (Figure 4b). In the structure, there are also sodium cations, which are connected to the carboxylate oxygen atoms O 5 and O 1 and to the $\mathrm{O}(3)^{\# 6}, \mathrm{O}(3)^{\# 7}, \mathrm{O}(6)^{\# 8}, \mathrm{O}(4)^{\# 6}$, and $\mathrm{O}(2)^{\# 5}$ atoms, connecting the $[\mathrm{Cu}$ (cpida)] chains (Figure 4 c ). The packing of 3 viewed along the $b$ axis is depicted in Figure 4d.

Table 3. Selected bond distances ( $\AA$ ) for the coordination center in compounds 3 and $4^{\dagger}$.

| Compound 3 |  | 4 |  |
| :---: | :---: | :---: | :---: |
| Distances |  |  |  |
| $\mathrm{Cu}(1)-\mathrm{O}(1)^{\# 5}$ | 1.935(4) | $\mathrm{Cu}(1)-\mathrm{O}(5)$ | 1.903(2) |
| $\mathrm{Cu}(1)-\mathrm{O}(5)$ | 1.892(4) | $\mathrm{Cu}(1)-\mathrm{O}(3)$ | 1.947(2) |

Figure 4. (a) Asymmetric unit of compound 3 with labeling. Thermal ellipsoids are shown at $50 \%$ probability; (b) Zig-zag motif of [Cu(cpida)] $]^{-}$fragments in 3 . Hydrogen atoms and sodium ions are omitted for clarity; (c) coordination environment of sodium ions; (d) packing of $\mathbf{3}$ viewed along the $b$ axis. Hydrogen atoms are omitted for clarity.

### 3.4. Crystal Structure of $\mathrm{Na}[\mathrm{Cu}(c \mathrm{cpida})] \cdot 2 \mathrm{H}_{2} \mathrm{O}$ (4)

Compound 4 crystallizes in the orthorhombic Iba2 space group (Table 1). Selected bond lengths and angles for 4 are displayed in Table 3 and Table S2 (Supporting Information). The composition of the asymmetric unit (Figure 5a) is like that of 3 . It contains the $[\mathrm{Cu} \text { (cpida) }]^{-}$anion with the cpida ${ }^{3-}$ ligand coordinated to the Cu cation in a tridentate fashion. The coordination sphere of the copper center is square planar, with the donor atoms being $\mathrm{N} 1, \mathrm{O} 5, \mathrm{O} 3$, and the $\mathrm{O} 1^{\# 9}$ atom of a neighboring [ Cu (cpida)] unit, with a $\mathrm{Cu}-\mathrm{N}$ distance of 2.054(3) $\AA$ and an average $\mathrm{Cu}-\mathrm{O}$ distance of 1.93(2) $\AA$. The O1 atom is located in an axial position, at a longer $\mathrm{Cu} 1-\mathrm{O} 1$ distance. Again, the [ Cu (cpida)] fragments form a chain-like structure, in a zig-zag motif (Figure 5b). In the structure, there are also sodium cations that are connected to the carboxylate oxygen atoms $\mathrm{O} 5, \mathrm{O} 1, \mathrm{O}(3)^{\# 10}, \mathrm{O}(3)^{\# 11}$, $\mathrm{O}(6)^{\# 12}, \mathrm{O}(4)^{\# 10}$, and $\mathrm{O}(2)^{\# 9}$, resulting in the overall stabilization of the [Cu(cpida)] chains (Figure 5c). Water crystallization molecules are present in the unit cell but, unfortunately, it was impossible to model it correctly and, therefore, a squeeze method was applied in this case. The analysis of the solvent mask we calculated gave $136 \mathrm{e}^{-}$in a volume of $446 \AA^{3}$ in a void per unit cell. This is consistent with the presence of two water molecules per asymmetric unit. The total amount of solvent calculated through this procedure (solvent mask, squeeze) also reasonably matches the elemental analysis and the $8.0 \%$ mass loss observed in TGA up to $120^{\circ} \mathrm{C}$ (Figure S6), with a calculated mass of $9.6 \%$ (two $\mathrm{H}_{2} \mathrm{O}$ molecules per $\mathrm{Na}\left[\mathrm{Cu}(\right.$ cpida) $\left.] \cdot 2 \mathrm{H}_{2} \mathrm{O}\right)$. The packing of 4 is depicted in Figure 5 d .

Figure 5. (a) Asymmetric unit of the structure of compound 4 with labeling. Thermal ellipsoids are shown at $50 \%$ probability. (b) Zig-zag motif of $[\mathrm{Cu} \text { (cpida) }]^{-}$fragments in 4 . Hydrogen atoms and sodium ions are omitted for clarity. (c) Coordination environment of sodium ions. (d) Packing of compound 4 , with view along the $c$ axis. Hydrogen atoms are omitted for clarity.

## 4. Conclusions

In this work, we have reported the structure of four new $\mathrm{Cu}(\mathrm{II})$ polymeric complexes derived from the 2-(carboxyphenyl)iminodiacetic acid, $\mathrm{H}_{3}$ cpida, obtained under different crystal growing conditions.

Compounds $\left[\mathrm{Cu}_{2}\right.$ (cpida) $\left.\left(\mathrm{H}_{2} \mathrm{O}\right)_{4}\right][\mathrm{Cu}$ (cpida) $] \cdot 3 \mathrm{H}_{2} \mathrm{O}(1)$ and $\left[\mathrm{Cu}_{2}(\right.$ cpida $\left.)\left(\mathrm{H}_{2} \mathrm{O}\right)_{4}\right][\mathrm{Cu}$ (cpida) $] \cdot \mathrm{H}_{2} \mathrm{O} \cdot 1 / 2 \mathrm{EtOH}(2)$, obtained through the evaporation of the solvent and ethanol vapor diffusion, respectively, are ionic, formed by the $\left[\mathrm{Cu}(\text { cpida) }]^{-}\right.$anion and the $\left[\mathrm{Cu}_{2}\right.$ (cpida) $\left.\left(\mathrm{H}_{2} \mathrm{O}\right)_{4}\right]^{+}$cation, both of them 1D coordination polymers. The structure of the anion is based on $[\mathrm{Cu}$ (cpida)] units connected by an acetic oxygen atom that is bridging the Cu centers in a chain-like structure. The $\left[\mathrm{Cu}_{2}(\text { cpida })\left(\mathrm{H}_{2} \mathrm{O}\right)_{4}\right]^{+}$cation is dinuclear and it is formed by [Cu(cpida)] units connected by one of the acetic carboxylate groups, while the phenyl carboxylate group is bridging a second copper (II) ion whose coordination sphere is completed with water molecules. Solvent molecules are present in the unit cells of both compounds.

Through diffusion of acetone or methanol vapors, compounds 3, $\mathrm{Na}[\mathrm{Cu}$ (cpida)], and $4, \mathrm{Na}[\mathrm{Cu}($ cpida $)] \cdot 2 \mathrm{H}_{2} \mathrm{O}$, are crystallized. They are also polymeric, with one of the acetic carboxylate groups of the ligand bridging the $\mathrm{Cu}(\mathrm{II})$ ions, forming an anionic chain-like structure. The sodium cations are balancing the negative charge, interacting with the oxygen atoms of different carboxylate groups, and connecting the $[\mathrm{Cu} \text { (cpida) }]_{n}$ chains.

#### Abstract

A series of molybdenum(VI) complexes with aryl-functionalized alkyl dihydrazones was prepared by the reaction of $\left[\mathrm{MoO}_{2}(\mathrm{acac})_{2}\right]$ and the appropriate dihydrazone in methanol. Their solid-state structures were elucidated via single-crystal X-ray diffraction (SC-XRD) and Fouriertransform infra-red (FTIR) spectroscopy, while the thermal stability of compounds was inspected by combined thermogravimetric analysis (TGA) and differential scanning calorimetry (DSC) experiments. The behaviour of complexes in DMSO- $d_{6}$ solution was explored by nuclear magnetic resonance (NMR). The relevant data show that all complexes are dinuclear, with dihydrazones acting as ditopic hexadentate ligands. The in vitro cytotoxic activity of the prepared molybdenum(VI) complexes was evaluated on THP-1 and HepG2 cell lines, while their antibacterial activity was tested against Staphylococcus aureus, Enterococcus faecalis, Escherichia coli, and Moraxella catarrhalis bacteria. The majority of compounds proved to be non-cytotoxic, while some exhibited superior antibacterial activity in comparison to dihydrazone ligands.

Keywords: hydrazones; $\mathrm{Mo}(\mathrm{VI})$ complexes; structural analysis; NMR spectroscopy; cytotoxic and antibacterial activity

## 1. Introduction

Over the last few decades, hydrazones have emerged as the privileged class of ligands owing to their stability, acid-base properties, and structural modularity [1]. Hydrazones are recognized for their remarkable coordination chemistry, which arises from their ability to act as flexible ligands, forming stable complexes with various metals [2]. This flexibility is attributed to the hydrazone's nitrogen and oxygen atoms, which can engage in both chelating and bridging modes in metal-organic frameworks (MOFs) [3]. Such features make them suitable for the development of metal-organic assemblies for specialized applications related to, e.g., magnetism, catalysis [4], or biomedicine [5-8]. Furthermore, the prospect of $E / Z$ isomerization, particularly as a response to different stimuli, such as light, pH , or heat, renders these systems suitable for the design of molecular switches or even more complex stimuli-responsive metal-organic architectures [9,10]. On the other hand, appropriate modification of the hydrazonic scaffolds can give rise to metal or covalentorganic frameworks for practical applications such as gas storage or separations [11].

By introducing more than one hydrazonic functionality within the same ligand molecule, and thus enhancing its coordination potential, one can target more complex metalorganic structures and functions as compared to the monohydrazone counterparts [12]. Multihydrazones, particularly those with alkyl chains, exhibit enhanced flexibility and can form more intricate and dynamic structures [13]. A notable example is the alkyl dihydrazone-based multinuclear Cu cages, which have been studied for their unique magnetic properties $[14,15]$. Structures of this type have also shown properties like
magnetic refrigeration and slow magnetic relaxation, which could have a number of promising applications [16].

Complexation with appropriate metal cations is often beneficial when one aims to modulate the bioactivity of the related organic entities [17,18]. For monohydrazones, whose antibacterial, antifungal, and antitumor properties have been widely acclaimed [19-22], derivatization via metal cation coordination has proven to be a viable route towards complexes with altered or enhanced biological properties [23]. The flexible nature of succinyl and adipoyl dihydrazones and its influence on the properties of the corresponding complexes, coupled with the fact that dihydazones have been considerably less investigated as bioactive compounds [24], motivated us to explore the cytotoxic and antibacterial activity of dihydrazone-based $\mathrm{Mo}(\mathrm{VI})$ complexes and compare it with those of the free ligands [25].

Here, we present a solid-state and a solution study of a series of dinuclear molybdenum(VI) complexes with aryl-functionalized alkyl dihydrazones. Namely, we provide simple synthetic routes towards the title compounds, accompanied by their thorough solid-state analysis via single-crystal X-ray diffraction (SCXRD), Fourier-transform infra-red (FTIR) spectroscopy, and simultaneous thermogravimetry and differential scanning calorimetry (TGA-DSC). In DMSO- $d_{6}$ solution, complexes were explored by nuclear magnetic resonance (NMR), unveiling symmetrical structures comparable with those established in the solid state. Finally, we focused on an evaluation of the cytotoxic and antibacterial activities of the obtained compounds against selected human cancer cell lines, and Gram-positive and Gram-negative bacterial strains, respectively.

## 2. Materials and Methods

### 2.1. Synthesis

Succinic dihydrazones of salicylaldehyde $\left(\mathbf{H}_{4} \mathbf{L}^{\mathbf{1}}\right)$, 2-hydroxy-1-naphtaldehyde $\left(\mathbf{H}_{4} \mathrm{~L}^{\mathbf{2}}\right)$ 2,3-dihydroxybenzaldehyde $\left(\mathrm{H}_{4} \mathrm{~L}^{3}\right)$, and 2,4-dihydroxybenzaldehyde $\left(\mathrm{H}_{4} \mathrm{~L}^{4}\right)$, as well as adipic dihydrazones of salicylaldehyde $\left(H_{4} L^{5}\right)$, 2-hydroxy-1-naphtaldehyde $\left(H_{4} L^{6}\right)$ 2,3-dihydroxybenzaldehyde $\left(H_{4} \mathbf{L}^{7}\right)$, and 2,4-dihydroxybenzaldehyde $\left(H_{4} \mathbf{L}^{8}\right)$ were prepared by a previously published procedure [15]. [ $\mathrm{MoO}_{2}(\mathrm{acac})_{2}$ ] was synthesized by a well-established synthetic protocol [26]. Chemicals for the synthesis were purchased from TCI and used as received. Methanol, used in syntheses, was purchased from Kemika (Zagreb, Croatia).

In general, complexes were prepared by the reaction of two equivalents of $\left[\mathrm{MoO}_{2}(\mathrm{acac})_{2}\right]$ and one equivalent of selected dihydrazone suspended in methanol (Supplementary Materials, Scheme S1). The resulting suspensions were refluxed for two hours, during which the ligands slowly reacted. Upon cooling, the crystalline material that was deposited was filtered, washed with a small amount of cold methanol, and dried in air.

### 2.1.1. Synthesis of $\left[\mathrm{Mo}_{2} \mathrm{O}_{4}(\mathrm{MeOH})_{2}\left(\mathrm{~L}^{1}\right)\right] \cdot \mathbf{2 M e O H}$

Obtained by the reaction of $0.5 \mathrm{mmol}(175 \mathrm{mg})$ of $\mathbf{H}_{4} \mathbf{L}^{\mathbf{1}}$ and $1.0 \mathrm{mmol}(326 \mathrm{mg})$ of $\left[\mathrm{MoO}_{2}(\mathrm{acac})_{2}\right]$ in 20 mL of methanol. Orange powder. Yield: $0.32 \mathrm{~g}(88 \%)$. Anal. Calcd. For $\mathrm{Mo}_{2} \mathrm{C}_{22} \mathrm{H}_{30} \mathrm{~N}_{4} \mathrm{O}_{8}$ (734.42): C, $35.98 \%, \mathrm{H}, 4.12 \%$, $\mathrm{N}, 7.63 \%$, found: C, $35.98 \%, \mathrm{H}$, $4.12 \%, \mathrm{~N}, 7.86 \%$. IR spectroscopy: $1615,1599 v(\mathrm{C}=\mathrm{N}) ; 1556,1541 v(\mathrm{C}=\mathrm{C}) ; 1338 v\left(\mathrm{C}-\mathrm{O}_{\mathrm{en}}\right)$; $1270 v\left(\mathrm{C}-\mathrm{O}_{\text {phen }}\right) ; 1011 v\left(\mathrm{C}-\mathrm{O}_{\mathrm{MeOH}}\right) ; 935 v_{\text {sym }}\left(\mathrm{MoO}_{2}\right) ; 907 v_{\text {asym }}\left(\mathrm{MoO}_{2}\right)$. TGA analysis: MeOH calcd. $17.45 \%$, found $17.84 \%$; $\mathrm{MoO}_{3}$ calcd. $39.20 \%$, found $36.83 \%$.

### 2.1.2. Synthesis of $\left[\mathrm{Mo}_{2} \mathrm{O}_{4}(\mathrm{MeOH})_{2}\left(\mathrm{~L}^{2}\right)\right]$

Obtained by the reaction of $0.5 \mathrm{mmol}(225 \mathrm{mg})$ of $\mathbf{H}_{4} \mathbf{L}^{2}$ and $1.0 \mathrm{mmol}(326 \mathrm{mg})$ of [ $\mathrm{MoO}_{2}(\mathrm{acac})_{2}$ ] in 20 mL of methanol. Yellow-orange powder. Yield: $0.29 \mathrm{~g}(76 \%)$. Anal. Calcd. For $\mathrm{Mo}_{2} \mathrm{C}_{28} \mathrm{H}_{26} \mathrm{~N}_{4} \mathrm{O}_{6}$ (770.45): C, $43.65 \%, \mathrm{H}, 3.4 \%, \mathrm{~N}, 7.27 \%$, found: C, $41.47 \%, \mathrm{H}$, $3.37 \%$, N, $7.05 \%$. IR spectroscopy: 1615, $1596 v(\mathrm{C}=\mathrm{N}) ; 1550,1534 v(\mathrm{C}=\mathrm{C}) ; 1329 v\left(\mathrm{C}-\mathrm{O}_{\mathrm{en}}\right)$; $1278 v\left(\mathrm{C}-\mathrm{O}_{\text {phen }}\right) ; 1012 v\left(\mathrm{C}-\mathrm{O}_{\mathrm{MeOH}}\right) ; 934 v_{\text {sym }}\left(\mathrm{MoO}_{2}\right) ; 907 v_{\text {asym }}\left(\mathrm{MoO}_{2}\right)$. TGA analysis: MeOH calcd. $8.32 \%$, found $9.80 \%$; $\mathrm{MoO}_{3}$ calcd. $37.37 \%$, found $34.26 \%$.

### 2.1.3. Synthesis of $\left[\mathrm{Mo}_{2} \mathrm{O}_{4}(\mathrm{MeOH})_{2}\left(\mathrm{~L}^{3}\right)\right] \cdot \mathbf{2 M e O H}$

Obtained by the reaction of $0.5 \mathrm{mmol}(191 \mathrm{mg})$ of $\mathbf{H}_{4} \mathrm{~L}^{3}$ and $1.0 \mathrm{mmol}(326 \mathrm{mg})$ of $\left[\mathrm{MoO}_{2}(\mathrm{acac})_{2}\right]$ in 20 mL of methanol. Red powder. Yield: $0.33 \mathrm{~g}(93 \%)$. Anal. Calcd. For $\mathrm{Mo}_{2} \mathrm{C}_{20} \mathrm{H}_{22} \mathrm{~N}_{4} \mathrm{O}_{8}$ (702.33): C, $34.2 \%, \mathrm{H}, 3.16 \%, \mathrm{~N}, 7.98 \%$, found: $\mathrm{C}, 33.52 \%, \mathrm{H}, 3.29 \%, \mathrm{~N}$, $7.98 \%$. IR spectroscopy: $1603 v(\mathrm{C}=\mathrm{N}) ; 1568,1538 v(\mathrm{C}=\mathrm{C}) ; 1340 v\left(\mathrm{C}-\mathrm{O}_{\mathrm{en}}\right) ; 1260 v\left(\mathrm{C}-\mathrm{O}_{\text {phen }}\right)$; $1015 v\left(\mathrm{C}-\mathrm{O}_{\mathrm{MeOH}}\right) ; 933 v_{\text {sym }}\left(\mathrm{MoO}_{2}\right) ; 901 v_{\text {asym }}\left(\mathrm{MoO}_{2}\right)$. TGA analysis: MeOH calcd. $16.72 \%$, found $17.09 \% ; \mathrm{MoO}_{3}$ calcd. $37.56 \%$, found $36.23 \%$.

### 2.1.4. Synthesis of $\left[\mathrm{Mo}_{2} \mathrm{O}_{4}(\mathbf{M e O H})_{2}\left(\mathrm{~L}^{4}\right)\right]$

Obtained by the reaction of $0.5 \mathrm{mmol}(191 \mathrm{mg})$ of $\mathbf{H}_{4} \mathrm{~L}^{4}$ and $1.0 \mathrm{mmol}(326 \mathrm{mg})$ of $\left[\mathrm{MoO}_{2}(\mathrm{acac})_{2}\right]$ in 20 mL of methanol. Red powder. Yield: $0.29 \mathrm{~g}(76 \%)$. Anal. Calcd. For $\mathrm{Mo}_{2} \mathrm{C}_{22} \mathrm{H}_{30} \mathrm{~N}_{4} \mathrm{O}_{10}$ (766.41): C, $34.48 \%, \mathrm{H}, 3.95 \%, \mathrm{~N}, 7.31 \%$, found: $\mathrm{C}, 35.17 \%, \mathrm{H}, 4.11 \%, \mathrm{~N}$, $7.31 \%$. IR spectroscopy: $1609 v(\mathrm{C}=\mathrm{N}) ; 1571,1549 v(\mathrm{C}=\mathrm{C}) ; 1334,1315 v\left(\mathrm{C}-\mathrm{O}_{\mathrm{en}}, \mathrm{C}-\mathrm{O}_{\text {phen }}\right)$; $1014 v\left(\mathrm{C}-\mathrm{O}_{\mathrm{MeOH}}\right) ; 944 v_{\text {sym }}\left(\mathrm{MoO}_{2}\right) ; 873 v_{\text {asym }}\left(\mathrm{MoO}_{2}\right)$. TGA analysis: MeOH calcd. $9.12 \%$, found $8.54 \% ; \mathrm{MoO}_{3}$ calcd. $40.99 \%$, found $39.99 \%$.

### 2.1.5. Synthesis of $\left[\mathrm{Mo}_{2} \mathrm{O}_{4}(\mathrm{MeOH})_{2}\left(\mathrm{~L}^{5}\right)\right]$

Obtained by the reaction of $0.5 \mathrm{mmol}(189 \mathrm{mg})$ of $\mathbf{H}_{4} \mathbf{L}^{5}$ and $1.0 \mathrm{mmol}(326 \mathrm{mg})$ of $\left[\mathrm{MoO}_{2}(\mathrm{acac})_{2}\right]$ in 20 mL of methanol. Orange powder. Yield: $0.28 \mathrm{~g}(80 \%)$. Anal. Calcd. For $\mathrm{Mo}_{2} \mathrm{C}_{22} \mathrm{H}_{26} \mathrm{~N}_{4} \mathrm{O}_{6}$ (698.38): C, $37.84 \%, \mathrm{H}, 3.75 \%$, N, $8.02 \%$, found: C, $38.22 \%, \mathrm{H}$, $3.6 \%$, N, $7.94 \%$. IR spectroscopy: 1611, $1596 v(\mathrm{C}=\mathrm{N}) ; 1558,1546 v(\mathrm{C}=\mathrm{C}) ; 1321 v\left(\mathrm{C}-\mathrm{O}_{\mathrm{en}}\right)$; $1284,1270 v\left(\mathrm{C}-\mathrm{O}_{\text {phen }}\right) ; 1010 v\left(\mathrm{C}-\mathrm{O}_{\mathrm{MeOH}}\right) ; 935 v_{\text {sym }}\left(\mathrm{MoO}_{2}\right) ; 880 v_{\text {asym }}\left(\mathrm{MoO}_{2}\right)$. TGA analysis: MeOH calcd. $9.18 \%$, found $10.15 \%$; $\mathrm{MoO}_{3}$ calcd. $41.22 \%$, found $39.30 \%$.

### 2.1.6. Synthesis of $\left[\mathrm{Mo}_{2} \mathrm{O}_{4}(\mathrm{MeOH})_{2}\left(\mathrm{~L}^{6}\right)\right]$

Obtained by the reaction of $0.5 \mathrm{mmol}(239 \mathrm{mg})$ of $\mathbf{H}_{4} \mathbf{L}^{6}$ and $1.0 \mathrm{mmol}(326 \mathrm{mg})$ of [ $\left.\mathrm{MoO}_{2}(\mathrm{acac})_{2}\right]$ in 20 mL of methanol. Yellow-orange powder. Yield: $0.38 \mathrm{~g}(95 \%)$. Anal. Calcd. For $\mathrm{Mo}_{2} \mathrm{C}_{30} \mathrm{H}_{30} \mathrm{~N}_{4} \mathrm{O}_{6}$ (798.5): C, $45.13 \%, \mathrm{H}, 3.79 \%, \mathrm{~N}, 7.02 \%$, found: C, $44.68 \%, \mathrm{H}$, $3.64 \%, \mathrm{~N}, 6.67 \%$. IR spectroscopy: 1618, $1599 v(\mathrm{C}=\mathrm{N}) ; 1551,1533 v(\mathrm{C}=\mathrm{C}) ; 1329 v\left(\mathrm{C}-\mathrm{O}_{\mathrm{en}}\right)$; $1277 v\left(\mathrm{C}-\mathrm{O}_{\text {phen }}\right) ; 1000 v\left(\mathrm{C}-\mathrm{O}_{\mathrm{MeOH}}\right) ; 937 v_{\text {sym }}\left(\mathrm{MoO}_{2}\right) ; 904 v_{\text {asym }}\left(\mathrm{MoO}_{2}\right)$. TGA analysis: MeOH calcd. $8.03 \%$, found $9.78 \%$; $\mathrm{MoO}_{3}$ calcd. $36.05 \%$, found $35.89 \%$.

### 2.1.7. Synthesis of $\left[\mathrm{Mo}_{2} \mathrm{O}_{4}(\mathbf{M e O H})_{2}\left(\mathrm{~L}^{7}\right)\right]$

Obtained by the reaction of $0.5 \mathrm{mmol}(205 \mathrm{mg})$ of $\mathbf{H}_{4} \mathrm{~L}^{7}$ and $1.0 \mathrm{mmol}(326 \mathrm{mg})$ of $\left[\mathrm{MoO}_{2}(\mathrm{acac})_{2}\right]$ in 20 mL of methanol. Red powder. Yield: $0.29 \mathrm{~g}(79 \%)$. Anal. Calcd. For $\mathrm{Mo}_{2} \mathrm{C}_{22} \mathrm{H}_{26} \mathrm{~N}_{4} \mathrm{O}_{8}$ (730.38): C, $36.18 \%$, H, $3.59 \%$, $\mathrm{N}, 7.67 \%$, found: $\mathrm{C}, 35.82 \%, \mathrm{H}, 3.66 \%, \mathrm{~N}$, $8.05 \%$. IR spectroscopy: $1603 v(\mathrm{C}=\mathrm{N}) ; 1569,1551 v(\mathrm{C}=\mathrm{C}) ; 1324 v\left(\mathrm{C}-\mathrm{O}_{\mathrm{en}}\right) ; 1263 v\left(\mathrm{C}-\mathrm{O}_{\text {phen }}\right)$; $1035 v\left(\mathrm{C}-\mathrm{O}_{\mathrm{MeOH}}\right) ; 939 v_{\text {sym }}\left(\mathrm{MoO}_{2}\right) ; 907,878 v_{\text {asym }}\left(\mathrm{MoO}_{2}\right)$. TGA analysis: MeOH calcd. $8.77 \%$, found $9.11 \% ; \mathrm{MoO}_{3}$ calcd. $39.42 \%$, found $38.07 \%$.

### 2.1.8. Synthesis of $\left[\mathrm{Mo}_{2} \mathrm{O}_{4}(\mathrm{MeOH})_{2}\left(\mathrm{~L}^{8}\right)\right] \cdot 2 \mathrm{MeOH}$

Obtained by the reaction of $0.5 \mathrm{mmol}(205 \mathrm{mg})$ of $\mathbf{H}_{4} \mathbf{L}^{8}$ and $1.0 \mathrm{mmol}(326 \mathrm{mg})$ of $\left[\mathrm{MoO}_{2}(\mathrm{acac})_{2}\right]$ in 20 mL of methanol. Red powder. Yield: $0.33 \mathrm{~g}(84 \%)$. Anal. Calcd. For $\mathrm{Mo}_{2} \mathrm{C}_{24} \mathrm{H}_{34} \mathrm{~N}_{4} \mathrm{O}_{10}$ (794.46): C, $36.28 \%, \mathrm{H}, 4.31 \%, \mathrm{~N}, 7.05 \%$, found: C, $37.01 \%, \mathrm{H}, 4.44 \%, \mathrm{~N}$, $7.33 \%$. IR spectroscopy: $1596 v(\mathrm{C}=\mathrm{N}) ; 1568,1553 v(\mathrm{C}=\mathrm{C}) ; 1333 v\left(\mathrm{C}-\mathrm{O}_{\mathrm{en}}\right) ; 1292 v\left(\mathrm{C}-\mathrm{O}_{\text {phen }}\right)$; $1016 v\left(\mathrm{C}-\mathrm{O}_{\mathrm{MeOH}}\right) ; 940 v_{\text {sym }}\left(\mathrm{MoO}_{2}\right) ; 885 v_{\text {asym }}\left(\mathrm{MoO}_{2}\right)$. TGA analysis: MeOH calcd. 16.13\%, found $16.13 \% ; \mathrm{MoO}_{3}$ calcd. $36.24 \%$, found $34.87 \%$.

### 2.2. Methods

The chemical composition analysis for carbon, hydrogen, and nitrogen was conducted at the Analytical Services Laboratory, Ruđer Bošković Institute (Zagreb, Croatia). X-ray powder diffraction patterns of the samples were obtained using an Empyrean diffractometer (Malvern Panalytical, Almelo, The Netherlands) utilizing copper K $\alpha$ radiation.

Measurements were made using zero-background holders and the Bragg-Brentano setup, covering a $2 \theta$ range of $4^{\circ}$ to $40^{\circ}$. Attenuated total reflectance Fourier transform infrared (ATR-FTIR) spectra were acquired with a Nicolet iS50 spectrometer (Thermo Fisher Scientific, Waltham, MA, USA). The thermal behaviour of the samples was analysed using a Mettler Toledo TGA/DSC 3+ thermobalance (Mettler Toledo, Columbus, OH, USA), employing aluminium crucibles under a nitrogen flow of 50 mL per minute, across a temperature spanning from $25^{\circ} \mathrm{C}$ to $600^{\circ} \mathrm{C}$ at a heating rate of $10^{\circ} \mathrm{C}$ per minute. Analysis of these experiments was performed using Mettler Toledo STARe Evaluation Software version 16.10.

Single crystals of suitable quality of $\left[\mathrm{Mo}_{2} \mathrm{O}_{4}(\mathrm{MeOH})_{2}\left(\mathrm{~L}^{1}\right)\right] \cdot 2 \mathrm{MeOH},\left[\mathrm{Mo}_{2} \mathrm{O}_{4}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}\left(\mathrm{~L}^{2}\right)\right]$, $\left[\mathrm{Mo}_{2} \mathrm{O}_{4}(\mathrm{MeOH})_{2}\left(\mathrm{~L}^{3}\right)\right] \cdot 2 \mathrm{MeOH}, \quad\left[\mathrm{Mo}_{2} \mathrm{O}_{4}(\mathrm{MeOH})_{2}\left(\mathrm{~L}^{4}\right)\right] \cdot 2 \mathrm{MeOH}, \quad\left[\mathrm{Mo}_{2} \mathrm{O}_{4}(\mathrm{MeOH})_{2}\left(\mathrm{~L}^{5}\right)\right]$, $\left[\mathrm{Mo}_{2} \mathrm{O}_{4}(\mathrm{MeOH})_{2}\left(\mathrm{~L}^{6}\right)\right],\left[\mathrm{Mo}_{2} \mathrm{O}_{4}(\mathrm{MeOH})_{2}\left(\mathrm{~L}^{7}\right)\right]$, and $\left[\mathrm{Mo}_{2} \mathrm{O}_{4}(\mathrm{MeOH})_{2}\left(\mathrm{~L}^{8}\right)\right] \cdot 2 \mathrm{MeOH}$ were obtained from diluted methanol solutions. Crystallographic data for $\left[\mathrm{Mo}_{2} \mathrm{O}_{4}(\mathrm{MeOH})_{2}\left(\mathrm{~L}^{3}\right)\right] \cdot 2 \mathrm{MeOH}$ and $\left[\mathrm{Mo}_{2} \mathrm{O}_{4}(\mathrm{MeOH})_{2}\left(\mathrm{~L}^{4}\right)\right] \cdot 2 \mathrm{MeOH}$ were obtained using $\omega$-scans on an Oxford Xcalibur diffractometer with a 4-circle kappa goniometer and a CCD Sapphire 3 detector, using Mo K $\alpha$ radiation at room temperature. The remaining compounds' data were gathered using a Rigaku XtaLAB Synergy-S diffractometer with a Dualflex source and a HyPix detector at $170(1) \mathrm{K}$. The data processing was carried out with the CrysAlis software suite [27]. Detailed crystal and intensity data collection and refinement parameters are presented in Supplementary Tables S1 and S2, and geometric data are reported in Tables S3-S7. Structure solution and refinement employed SHELXT [28] for dual space structure solution and SHELXL [29] for full-matrix least-squares refinement, treating non-hydrogen atoms anisotropically. Hydrogen atoms were modelled using geometrically idealized positions and the riding model, with their coordinates and distance constraints refined in later stages. The suite of SHELX programs was used within the Olex2 framework, [30] and Mercury 2021.3.0 software handled geometrical calculations and molecular graphics [31].

Nuclear Magnetic Resonance (NMR) spectroscopy was performed using a Bruker Avance III HD $400 \mathrm{MHz} / 54 \mathrm{~mm}$ Ascend spectrometer, equipped with a 5 mm PA BBI 1H/D BB Z-GRAD probehead. The range of experiments included 1D $\left({ }^{1} \mathrm{H},{ }^{13} \mathrm{C}\right.$-DEPTq $)$ and 2D (COSY, ${ }^{1} \mathrm{H}-{ }^{13} \mathrm{C}$ HSQC, ${ }^{1} \mathrm{H}-{ }^{13} \mathrm{C}$ HMBC, ${ }^{1} \mathrm{H}-{ }^{15} \mathrm{~N}$ HSQC, ${ }^{1} \mathrm{H}-{ }^{15} \mathrm{~N}$ HMBC) techniques, conducted at room temperature. DMSO- $d 6$ served as the solvent, with TMS as the internal standard for proton and carbon shifts, and nitrogen shifts using liquid ammonia as the standard.

In vitro biological evaluations were carried out to assess the cytotoxic effects of the complexes against cute monocytic leukaemia (THP-1) and hepatocellular carcinoma (HepG2) human cell lines, using the MTS assay as per established protocols [32]. The antibacterial efficacy of the complexes was tested against two Gram-positive bacteria (Staphylococcus aureus and Enterococcus faecalis) and two Gram-negative bacteria (Escherichia coli and Moraxella catarrhalis) using the broth microdilution method, adhering to CLSI guidelines [33,34].

## 3. Results and Discussion

### 3.1. Synthesis and Solid-State Characterization

Synthesis of the dioxomolybdenum(VI) complexes proceeded straightforwardly when reacting the methanolic solution of $\left[\mathrm{MoO}_{2}(\mathrm{acac})_{2}\right]$ with a suspension of ligands in methanol. The limiting factor of the reaction was the poor solubility of the ligands in methanol (and in any solvent other than DMSO, for that matter); thus, the reaction mixture had to be heated under reflux for two hours to guarantee reaction completion. Qualitatively, the solubility of the ligands in methanol can be described with the following scheme: $\mathrm{H}_{4} \mathrm{~L}^{3,7} \approx \mathrm{H}_{4} \mathrm{~L}^{4,8}>\mathrm{H}_{4} \mathrm{~L}^{1,5}>\mathrm{H}_{4} \mathrm{~L}^{2,6}$. This trend was also reflected in the reaction times, i.e., ligands derived from dihydroxyaldehydes reacted faster than those derived from salicylaldehyde and 2-hydroxynaphthaldehyde. Owing to the overall low solubility of the resulting complexes, the isolated products were, in all cases, obtained as fine powder, and the crystals were only obtained by crystallization from very diluted solutions. In the case of $\mathrm{Mo}(\mathrm{VI})$ complexes with $\mathrm{H}_{4} \mathrm{~L}^{2}$ and $\mathrm{H}_{4} \mathrm{~L}^{4}$ ligands, it should be noted that reactions
yielded $\left[\mathrm{Mo}_{2} \mathrm{O}_{4}(\mathrm{MeOH})_{2}\left(\mathrm{~L}^{2}\right)\right]$ and $\left[\mathrm{Mo}_{2} \mathrm{O}_{4}(\mathrm{MeOH})_{2}\left(\mathrm{~L}^{4}\right)\right]$, while the (re)crystallization of that material from diluted methanolic solutions gave single crystals of $\left[\mathrm{Mo}_{\mathbf{2}} \mathrm{O}_{\mathbf{4}}\left(\mathrm{H}_{\mathbf{2}} \mathrm{O}\right)_{\mathbf{2}}\left(\mathrm{L}^{2}\right)\right.$ ] and $\left[\mathrm{Mo}_{2} \mathrm{O}_{4}(\mathrm{MeOH})_{2}\left(\mathrm{~L}^{4}\right)\right] \cdot 2 \mathrm{MeOH}$, respectively. This is confirmed by a comparison of the PXRD data (Supplementary Materials, Figures S19-S26) with the simulated powder patterns obtained from crystal structure data (vide infra).

The thermal behavior of the prepared bulk complexes (Supplementary Materials, Figures S11-S18) is somewhat independent of the ligand choice and, expectedly, dependent on the presence of uncoordinated methanol molecules in the crystal. Interestingly, all methanol molecules (both coordinated and uncoordinated) are driven out of the bulk phase concomitantly, i.e., no separate steps are observed. As expected for molybdenum(VI) hydrazone complexes, at high temperatures, the materials undergo a complex sequence of decompositions, finally yielding $\mathrm{MoO}_{3}$ above $\sim 450{ }^{\circ} \mathrm{C}$ in an oxygen atmosphere. The mass fraction of the $\mathrm{MoO}_{3}$ obtained through TGA analysis is consistent with the expected Mo:ligand ratio of 2:1.

Single-crystal X-ray diffraction: A detailed survey of the relevant literature revealed only few examples of the molybdenum(VI) complexes with ligands of the type [35-37]. All complexes investigated in this study are dinuclear, with the succinyl- and adipoyltype ligands acting as ditopic hexadentate ones. The two compartments of each ligand coordinate in the hydrazonato form [38], after the deprotonation of $\mathrm{O} 1-\mathrm{H} 1$ and $\mathrm{O} 2-\mathrm{H} 2$ functionalities. In this way, the ligands behave as tetraanions, with their two compartments binding the two $\mathrm{MoO}_{2}{ }^{2+}$ units via O1, N1 and O2 donor atoms (Figures 1a,b and 2a,b; Supplementary Materials, Figures S1 and S2). The remaining coordination sites are occupied by the two oxido atoms, and an oxygen OH atom of ancillary methanol or, in the case of the $\left[\mathrm{Mo}_{2} \mathrm{O}_{4}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}\left(\mathrm{~L}^{2}\right)\right]$ complex, water molecule (Figure 1b). Consequently, the coordination geometry of each Mo atom can be described as a distorted octahedral geometry, with the shortest distances being $\mathrm{Mo}=\mathrm{O}$ ones, while those positioned trans to those are, expectedly, the longest within the coordination sphere. The Mo1 atom is, in all cases, shifted above the plane defined by the O1, N1, and O2 atoms towards the apical oxygen atom by $0.28-0.32$ for the succinyl-type complexes, whereas for the adipoyl ones these distances are larger, between ca 0.31 and 0.36 .

When considering the molecular structures of dinuclear complexes based on the succinyl-type of ligands, one observes that, except $\left[\mathbf{M o}_{2} \mathbf{O}_{\mathbf{4}}\left(\mathbf{H}_{\mathbf{2}} \mathrm{O}\right)_{2}\left(\mathrm{~L}^{2}\right)\right]$, the remaining ones are conformationally fairly similar (Figure 1c). Namely, conformations of complexes are staggered such that the planes defined by the aldehyde residues are parallel and distanced by ca $0.66,0.77$, and 0.80 for $\left[\mathrm{Mo}_{\mathbf{2}} \mathrm{O}_{\mathbf{4}}(\mathbf{M e O H})_{2}\left(\mathrm{~L}^{4}\right)\right],\left[\mathrm{Mo}_{\mathbf{2}} \mathrm{O}_{4}(\mathbf{M e O H})_{2}\left(\mathrm{~L}^{3}\right)\right]$, and $\left[\mathrm{Mo}_{2} \mathrm{O}_{4}(\mathrm{MeOH})_{2}\left(\mathrm{~L}^{1}\right)\right]$, respectively, whereas in the case of $\left[\mathrm{Mo}_{2} \mathrm{O}_{4}\left(\mathrm{H}_{\mathbf{2}} \mathrm{O}\right)_{2}\left(\mathrm{~L}^{2}\right)\right]$, this distance is ca 0.34 . Due to the longer bridge between the two compartments of the complex, conformational differences in the group of adipoyl-type complexes are larger (Figure 2c). Namely, the molecule of $\left[\mathrm{Mo}_{2} \mathrm{O}_{4}(\mathbf{M e O H})_{2}\left(\mathrm{~L}^{8}\right)\right]$ is essentially planar, while $\left[\mathrm{Mo}_{2} \mathrm{O}_{4}(\mathrm{MeOH})_{2}\left(\mathrm{~L}^{5}\right)\right]$, and $\left[\mathrm{Mo}_{2} \mathrm{O}_{4}(\mathrm{MeOH})_{2}\left(\mathrm{~L}^{7}\right)\right]$ adopt staggered conformations. Moreover, in $\left[\mathrm{Mo}_{2} \mathrm{O}_{4}(\mathbf{M e O H})_{2}\left(\mathrm{~L}^{6}\right)\right]$ and $\left[\mathrm{Mo}_{2} \mathrm{O}_{4}(\mathbf{M e O H})_{2}\left(\mathrm{~L}^{7}\right)\right]$, planes defined by the aldehyde residues are not parallel but form angles of ca $32^{\circ}$ and ca $26^{\circ}$, respectively.

In solvates of the succinyl-type of complexes, $\left[\mathrm{Mo}_{2} \mathrm{O}_{4}(\mathrm{MeOH})_{2}\left(\mathrm{~L}^{\mathbf{1}}\right)\right] \cdot \mathbf{2 M e O H}$, textbf $\left[\mathrm{Mo}_{2} \mathrm{O}_{4}(\mathrm{MeOH})_{2}\left(\mathrm{~L}^{3}\right)\right] \cdot 2 \mathrm{MeOH}$, and $\left[\mathrm{Mo}_{\mathbf{2}} \mathbf{O}_{\mathbf{4}}(\mathbf{M e O H})_{2}\left(\mathrm{~L}^{4}\right)\right] \cdot \mathbf{2 M e O H}$, non-coordinated methanol molecules bridge coordination entities by acting both as hydrogen bond donors and acceptors (Figures 3a and S3-S5). The situation is different in $\left[\mathrm{Mo}_{\mathbf{2}} \mathbf{O}_{4}\left(\mathbf{H}_{\mathbf{2}} \mathbf{O}\right)_{2}\left(\mathrm{~L}^{2}\right)\right]$, where the coordinated water molecules act solely as hydrogen bond donors to connect neighbouring complexes via $\mathrm{O}-\mathrm{H} \cdots \mathrm{N}$ and $\mathrm{O}-\mathrm{H} \cdots \mathrm{O}$ hydrogen bonds (Figures 3 b and S 6 ). The resulting supramolecular architectures are, in all cases, further supported and stabilized by a plethora of $\mathrm{C}-\mathrm{H} \cdots \mathrm{O}$ hydrogen bonds. Similarly, in the crystal structures of adipoyl-type complexes, supramolecular interactions are mediated through the only available hydrogen bond donors, the coordinated methanol OH and aryl hydroxy OH group, while hydrogen bond acceptors are either imide nitrogen atom or the axial $\left\{\mathrm{MoO}_{2}\right\}^{2+}$ oxygen atom (Figures 4 and S7-S10). The presence of non-coordinated methanol molecules
in the dual role of hydrogen bond donors and acceptors in $\left[\mathrm{Mo}_{2} \mathrm{O}_{4}(\mathrm{MeOH})_{2}\left(\mathrm{~L}^{8}\right)\right] \cdot \mathbf{2 M e O H}$ makes the hydrogen-bonded network comparatively richer (Figures $4 b$ and S10). Finally, as in the case of succinyl-type complexes, crystal structures in adipoyl-type of complexes are stabilized by a collection of $\mathrm{C}-\mathrm{H} \cdots \mathrm{O}$ hydrogen bonds.

Figure 1. Molecular structures of: (a) $\left[\mathrm{Mo}_{2} \mathrm{O}_{4}(\mathrm{MeOH})_{2}\left(\mathrm{~L}^{1}\right)\right] \cdot 2 \mathrm{MeOH}$ and (b) $\left[\mathrm{Mo}_{2} \mathrm{O}_{4}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}\left(\mathrm{~L}^{2}\right)\right]$ with the atom numbering schemes. The central aliphatic C 2 fragments of molecules lie on the inversion center. (c) Overlay of the molecular structures of $\left[\mathrm{Mo}_{2} \mathrm{O}_{4}(\mathbf{M e O H})_{2}\left(\mathrm{~L}^{1}\right)\right]$ (pink), $\left[\mathrm{Mo}_{2} \mathrm{O}_{4}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}\left(\mathrm{~L}^{2}\right)\right]$ (yellow), $\left[\mathrm{Mo}_{2} \mathrm{O}_{4}(\mathrm{MeOH})_{2}\left(\mathrm{~L}^{3}\right)\right]$ (blue), and $\left[\mathrm{Mo}_{2} \mathrm{O}_{4}(\mathrm{MeOH})_{2}\left(\mathrm{~L}^{4}\right)\right]$ (gray). In (a,b) displacement ellipsoids are drawn at the $50 \%$ probability level, while the hydrogen atoms are presented as spheres of arbitrary small radii. In (a), hydrogen bonds are highlighted by yellow dashed lines.

Molecular structures of: (a) $\left[\mathrm{Mo}_{2} \mathrm{O}_{4}(\mathrm{MeOH})_{2}\left(\mathrm{~L}^{5}\right)\right]$ and $(b)\left[\mathrm{Mo}_{2} \mathrm{O}_{4}(\mathrm{MeOH})_{2}\left(\mathrm{~L}^{8}\right)\right] \cdot \mathbf{2 M e O H}$ with the atom numbering schemes. The central aliphatic C 4 fragments of molecules sit on the inversion center. (c) Overlay of the molecular structures of $\left[\mathrm{Mo}_{2} \mathrm{O}_{4}(\mathrm{MeOH})_{2}\left(\mathrm{~L}^{5}\right)\right]$ (yellow), $\left[\mathrm{Mo}_{2} \mathrm{O}_{4}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}\left(\mathrm{~L}^{6}\right)\right]$ (grey), $\left[\mathrm{Mo}_{2} \mathrm{O}_{4}(\mathrm{MeOH})_{2}\left(\mathrm{~L}^{7}\right)\right]$ (red), and $\left[\mathrm{Mo}_{2} \mathrm{O}_{4}(\mathrm{MeOH})_{2}\left(\mathrm{~L}^{8}\right)\right]$ (blue). In (a,b) displacement ellipsoids are drawn at the $50 \%$ probability level, while the hydrogen atoms are presented as spheres of arbitrary small radii. In (a), hydrogen bonds are highlighted by yellow dashed lines.

Figure 3. Supramolecular architectures found in: (a) $\left[\mathrm{Mo}_{2} \mathrm{O}_{4}(\mathrm{MeOH})_{2}\left(\mathrm{~L}^{1}\right)\right] \cdot 2 \mathrm{MeOH}$ and (b) $\left[\mathrm{Mo}_{2} \mathrm{O}_{4}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}\left(\mathrm{~L}^{2}\right)\right]$. Hydrogen bonds are highlighted as yellow dashed lines.

Figure 4. Crystal packing in: (a) $\left[\mathrm{Mo}_{2} \mathrm{O}_{4}(\mathrm{MeOH})_{2}\left(\mathrm{~L}^{5}\right)\right]$ and (b) $\left[\mathrm{Mo}_{2} \mathrm{O}_{4}(\mathrm{MeOH})_{2}\left(\mathrm{~L}^{8}\right)\right] \cdot 2 \mathrm{MeOH}$. Hydrogen bonds are highlighted as yellow dashed lines.

### 3.2. NMR and FT-IR Spectroscopy

The chemical identities of the title complexes in DMSO- $d_{6}$ solutions at room temperature were established via ${ }^{1} \mathrm{H},{ }^{13} \mathrm{C}$, and ${ }^{15} \mathrm{~N}$ NMR spectroscopy (Supplementary Materials, Tables S8 and S9, Figures S27-S32). Relevant chemical shifts unveil that, in the DMSO solution, the explored dinuclear $\mathrm{Mo}(\mathrm{VI})$ complexes are symmetrical, since only one set of signals was observed in each case. Moreover, these complexes, unlike the related neutral ligands, in DMSO- $d_{6}$ solutions, dominantly adopt one isomeric form. The absence of hydroxyaryl O1-H1 and hydrazonic N2-H2 protons in the spectra of complexes confirms that coordinated ligands are present in their tetraanionic form. Moreover, the significant deshielding of the N2 nitrogen chemical shift in the complexes, in comparison to neutral ligands, along with the slight deshielding of the C 8 signal, confirms the enol-imino form of the coordinated ligands [39]. The ${ }^{1} \mathrm{H},{ }^{13} \mathrm{C}$, and ${ }^{15} \mathrm{~N}$ chemical shifts in complexes are comparable to those of neutral ligands. Finally, owing to the strong donor nature of the DMSO, the title complexes undergo a solvent exchange reaction, which has been previously described in the literature for a similar type of Mo complex [40].

FTIR-ATR spectra (Supplementary Materials, Figures S33-S40) show features characteristic of dioxomolybdenum(VI) hydrazone complexes. In contrast to the respective ligands [15], absorption peaks corresponding to $\mathrm{C}=\mathrm{O}$ stretching vibrations (usually found at $\sim 1650 \mathrm{~cm}^{-1}$ ) and those related to N-H stretching vibrations (at around $\sim 3200 \mathrm{~cm}^{-1}$ ) are absent in the spectra of prepared complexes. Thus, it can be concluded that the ligand is (tetra)deprotonated and in enol-imino form. However, the high-wave-number region of the spectra is rich, owing to the $\mathrm{O}-\mathrm{H}$ stretching vibrations of crystal and coordinated methanol molecules, and in the case of complexes derived from $\mathrm{H}_{4} \mathrm{~L}^{3}, \mathrm{H}_{4} \mathrm{~L}^{4}, \mathrm{H}_{4} \mathrm{~L}^{7}$, and $\mathrm{H}_{4} \mathrm{~L}^{8}$, additional phenolic $\mathrm{O}-\mathrm{H}$ bands. A significant shift to lower wavenumbers of the $\mathrm{C}=\mathrm{N}$ stretching bands ( $\sim 1590-1600 \mathrm{~cm}^{-1}$ ) compared to those of the free ligands ( $\sim 1610-1630 \mathrm{~cm}^{-1}$ ), together with the absence of the $\mathrm{C}=\mathrm{O}$ band, corroborates the coordination of the $\left\{\mathrm{MoO}_{2}\right\}^{2+}$ core by the ONO pincer-like compartment of the ligand in its hydrazonato form. The C-O stretching vibrations of the enolato and phenolato fragments can be found at ~1330 and $\sim 1270 \mathrm{~cm}^{-1}$, respectively. All complexes exhibit distinct bands at $\sim 930-940 \mathrm{~cm}^{-1}$ and
$\sim 880-910 \mathrm{~cm}^{-1}$, typical for dioxomolybdenum(VI) complexes, corresponding to symmetric and asymmetric $\left\{\mathrm{MoO}_{2}\right\}^{2+}$ core stretching vibrations, respectively [41]. Moreover, the spectra display bands indicative of coordinated methanol molecules, i.e., $\mathrm{C}-\mathrm{O}$ stretching vibrations at ca. 1010-1030 $\mathrm{cm}^{-1}$. Taken together, the spectroscopic data are consistent with the identities and structures of the prepared complexes obtained from SC-XRD experiments.

### 3.3. In Vitro Cytotoxic and Antibacterial Activity

The here-reported molybdenum(VI) complexes were tested for their cytotoxic activity against HepG2 and THP-1 cells, while their antibacterial activity was evaluated on S. aureus, E. faecalis, E. coli, and M. catarrhalis bacterial strains. The bioassay results are summarized in Table 1.

Table 1. The $\mathrm{IC}_{50}$ values and minimum inhibitory concentrations (MIC) of the Mo(VI) complexes.

| Compound | $\mathbf{I C}_{50}\left(\boldsymbol{\mu \mathrm { mol } \mathrm { L } ^ { - \mathbf { 1 } } )}\right.$ |  | MIC $\left(\boldsymbol{\mu \mathrm { g } \mathrm { mL }}{ }^{\mathbf{- 1})}\right.$ |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | THP-1 | HepG2 | S. aureus | E. faecalis | E. coli | M. catarrhalis |
| 1-Mo | 19.58 | $>100$ | $>256$ | 64 | $>256$ | 32 |
| 2-Mo | 7.04 | $>100$ | 32 | 32 | 32 | 4 |
| 3-Mo | $>100$ | $>100$ | 256 | 256 | 128 | 128 |
| 4-Mo | $>100$ | $>100$ | $>256$ | 128 | $>256$ | $>256$ |
| 5-Mo | $>100$ | $>100$ | $>256$ | $>256$ | $>256$ | $>256$ |
| 6-Mo | 9.78 | 57.98 | $>256$ | 128 | 128 | 2 |
| 7-Mo | $>100$ | $>100$ | $>256$ | 32 | 64 | 64 |
| 8-Mo | $>100$ | $>100$ | $>256$ | $>256$ | $>256$ | $>256$ |
| staurosporine | 0.10 | 7.98 | - | - | - |  |
| azithromycin | - | - | 1 | 8 | 0.50 | 0.125 |

1- $\mathrm{Mo}=\left[\mathrm{Mo}_{2} \mathrm{O}_{4}(\mathrm{MeOH})_{2}\left(\mathrm{~L}^{1}\right)\right] ; 2-\mathrm{Mo}=\left[\mathrm{Mo}_{2} \mathrm{O}_{4}(\mathrm{MeOH})_{2}\left(\mathrm{~L}^{2}\right)\right] ; 3-\mathrm{Mo}=\left[\mathrm{Mo}_{2} \mathrm{O}_{4}(\mathrm{MeOH})_{2}\left(\mathrm{~L}^{3}\right)\right] ; 4-\mathrm{Mo}=$ $\left[\mathrm{Mo}_{2} \mathrm{O}_{4}(\mathrm{MeOH})_{2}\left(\mathrm{~L}^{4}\right)\right] ; 5-\mathrm{Mo}=\left[\mathrm{Mo}_{2} \mathrm{O}_{4}(\mathrm{MeOH})_{2}\left(\mathrm{~L}^{5}\right)\right] ; 6-\mathrm{Mo}=\left[\mathrm{Mo}_{2} \mathrm{O}_{4}(\mathrm{MeOH})_{2}\left(\mathrm{~L}^{6}\right)\right] ; \quad 7-\mathrm{Mo}=\left[\mathrm{Mo}_{2} \mathrm{O}_{4}\right.$ $\left.(\mathrm{MeOH})_{2}\left(\mathrm{~L}^{7}\right)\right]$; and $8-\mathrm{Mo}=\left[\mathrm{Mo}_{2} \mathrm{O}_{4}(\mathrm{MeOH})_{2}\left(\mathrm{~L}^{8}\right)\right]$.

According to the results (Table 1), all of the investigated complexes were found to be noncytotoxic towards HepG2 cells, and, except $\left[\mathrm{Mo}_{2} \mathrm{O}_{\mathbf{4}}(\mathbf{M e O H})_{\mathbf{2}}\left(\mathrm{L}^{1}\right)\right],\left[\mathrm{Mo}_{\mathbf{2}} \mathrm{O}_{4}(\mathrm{MeOH})_{2}\left(\mathrm{~L}^{2}\right)\right]$ and $\left[\mathrm{Mo}_{2} \mathrm{O}_{4}(\mathrm{MeOH})_{2}\left(\mathrm{~L}^{6}\right)\right]$, which displayed only weak to moderate cytotoxicity, did not show any cytotoxic effects against THP-1. The results, given in Table 1, also reveal that complexes in general exhibited poor or no antibacterial activity, while some of them with MICs equal to $32 \mu \mathrm{~g} \mathrm{~mL}{ }^{-1}$ demonstrated mild activity. Only $\left[\mathrm{Mo}_{2} \mathbf{O}_{4}(\mathbf{M e O H})_{2}\left(\mathrm{~L}^{2}\right)\right]$ and $\left[\mathrm{Mo}_{2} \mathrm{O}_{4}(\mathbf{M e O H})_{2}\left(\mathrm{~L}^{6}\right)\right]$, with minimum inhibitory concentrations equal to 4 and $2 \mu \mathrm{~g} \mathrm{~mL}$, respectively, were proved to possess appreciable antibacterial potential towards $M$. catarrhalis.

Apart from $\left[\mathrm{Mo}_{2} \mathrm{O}_{4}(\mathrm{MeOH})_{2}\left(\mathrm{~L}^{1}\right)\right],\left[\mathrm{Mo}_{2} \mathrm{O}_{4}(\mathrm{MeOH})_{2}\left(\mathrm{~L}^{2}\right)\right]$, and $\left[\mathrm{Mo}_{2} \mathrm{O}_{4}(\mathrm{MeOH})_{2}\left(\mathrm{~L}^{6}\right)\right]$, chelation in general did not have a large influence on the cytotoxic properties of the examined compounds [15]. However, some differences in the antibacterial properties of $\mathrm{Mo}(\mathrm{VI})$ complexes in comparison with the corresponding free ligands were established. On the one hand, a noticeable reduction in antibacterial properties after the complexation to molybdenum was only observed for the anti-E. faecalis activity of $\mathrm{H}_{4} \mathrm{~L}^{5}$, as well as for the anti-E. faecalis and anti-E. coli activities of $\mathrm{H}_{4} \mathrm{~L}^{6}$. On the other hand, the bactericidal potency of $\left[\mathrm{Mo}_{2} \mathrm{O}_{4}(\mathrm{MeOH})_{2}\left(\mathrm{~L}^{2}\right)\right]$ and $\left[\mathrm{Mo}_{\mathbf{2}} \mathrm{O}_{4}(\mathbf{M e O H})_{2}\left(\mathrm{~L}^{7}\right)\right]$ complexes was demonstrated, along with the increased anti-M. catarrhalis activity of $\left[\mathbf{M o}_{2} \mathbf{O}_{\mathbf{4}}(\mathbf{M e O H})_{2}\left(\mathrm{~L}^{6}\right)\right]$, when compared to the neutral ligands.

## 4. Conclusions

A series of novel molybdenum(VI) complexes with succinyl and adipoyl dihydrazones was synthesized, characterized, and evaluated with respect to their biological activity. Conventional solution synthesis proved to be a straightforward route towards the title complexes, although it was to some extent limited by the solubility of the ligands. The structures of the complexes were explored via single-crystal X-ray diffraction and FTIR spectroscopy in the solid state, while their behavior in the DMSO- $d_{6}$ solution was studied
by the NMR technique. Structural studies unveiled that all complexes are dinuclear, with tetraanions of dihydrazones acting as flexible ditopic hexadentate ligands, both in the solid state and in DMSO solution. The complexes generally showed non-cytotoxic behavior towards HepG2 cells and varying degrees of cytotoxicity against THP-1 cells. Some exhibited mild antibacterial activity, with notable effectiveness against Moraxella catarrhalis. The results highlight the moderate improvement in antimicrobial properties compared to the respective ligands. These findings, combined with the facile modulation of the complexes of this type, could serve as a fruitful platform for the future development of this type of compound as potentially bioactive compounds.

[^0]:    ${ }^{1}$ The solvent molecule (THF) was severely disordered over many sites and could not be refined in a satisfactory manner. Therefore, the solvent was treated with SQUEEZE as implemented in PLATON [49-51]. This procedure detected per unit cell, solvent accessible volume of $562 \AA^{3}$, and contributions of 160 electrons therein (well in accord with 160 electrons for the four THF molecules per unit cell, which have been omitted from refinement). ${ }^{2}$ The solvent molecule (chloroform) was refined disordered over three sites with site occupancy factors $0.269(6)$, $0.316(4)$ and $0.415(6) .{ }^{3}$ The absolute structure parameter $\chi_{\text {Flack }}$ of this non-centrosymmetric structure refined to $-0.035(6)$.
