Abstract: The friction factor and heat transfer of Giesekus-fluid-based nanofluids in a pipe flow were studied in the ranges of 0.5 ≤ Reynolds number (Re) ≤ 500, 1 ≤ Weissenberg number (Wi) ≤ 8, 0.5% ≤ particle volume concentration (Φ) ≤ 3.0%, 0 ≤ viscosity ratio (β0) ≤ 1, and 0 ≤ mobility parameter (α) ≤ 0.5. Our numerical method was validated by comparing the results with available ones in the literature. The effects of Wi, Φ, β0, Re, and α on the relative friction factor (Cf/CfNew), Nusselt number (Nu), and ratio (PECnf/PECf) of energy performance evaluation criterion for Giesekus-fluid-based nanofluids to those for Giesekus fluid were discussed. The results showed that the values for the Cf/CfNew and Nu of Giesekus-fluid-based nanofluids were larger than those for Newtonian fluid-based nanofluids and those for pure Giesekus fluid. The values for Cf/CfNew increased with increasing Φ and Re, but they increased with decreasing β0 and α. As Wi increased, the values of Cf/CfNew first increased and then decreased. The values of Nu and PECnf/PECf were enhanced with increasing Wi, Φ, Re, and α, but with decreasing β0. It is more effective to use Giesekus-fluid-based nanofluids to improve heat transfer with the conditions of a larger Wi, Φ, Re, and α and a smaller β0. Finally, the correlation formula for PECnf/PECf as a function of Wi, Φ, β0, Re, and α was derived.

Keywords: friction factor; heat transfer; Giesekus-fluid-based nanofluids; pipe flow; numerical simulation

1. Introduction

The friction factor and heat transfer of non-Newtonian fluids have aroused extensive concern due to their wide range of applications, e.g., drilling processes, synthesis of composites, paper making, and plastic molding [1,2]. In order to reduce friction and increase the heat transfer of fluid flowing in a pipe and achieve the goal of saving energy, nanofluids, i.e., fluids containing nanoparticles, are used. So far, nanofluids have been extensively used, and their properties have also been widely investigated. For example, adding graphite and carbon nanofibers increases the efficiency of a gear pump-driven hydraulic circuit using ethanol [3]. The thermal efficiency was increased by 13.8%, 1.5%, and 1.3% for nanofluids of water–CuO compared with pure water, water–TiO2, and water–Al2O3, respectively [4]. Low friction factor and high heat transfer were reached when the nanofluids of water-Al2O3 and water-SiO2 were used in a heat exchanger in the range of 10,551 ≤ Re ≤ 17,220 and 17,220 ≤ Re ≤ 31,910, respectively [5]. Newtonian fluid was employed as the base fluid in most of the previous studies. However, there are many occasions where the base fluid is non-Newtonian fluid in applications; only a few studies have focused on non-Newtonian fluid as the base fluid. For instance, the Deborah number had an important impact on convective heat transfer, and the effect of heat...
conduction of Jeffrey nanofluids was better than that of Oldroyd-B nanofluids [6]. The impacts of fluid relaxation and retardation time parameters on the velocity of Oldroyd-B nanofluids were converse [7]. The heat transfer performance of Jeffrey nanofluids was better than that of the Oldroyd-B nanofluids when taking the thermal radiation, suction, and nonuniform heat source/sink into account [8]. The heat transfer performance was greatly enhanced in the Oldroyd-B nanofluids at higher Biot and Prandtl numbers [9]. The heat transfer rate of EG-Si$_3$N$_4$ was higher than that of EG for various nanoparticle concentrations and flow rates [10]. The heat transfer rate of Oldroyd-B nanofluids was much higher than those of Jeffery and Maxwell nanofluids, while the friction factor of Maxwell nanofluids was less than those of Oldroyd-B and Jeffrey nanofluids over a permeable stretching sheet [11]. Polyalphaolefins-based nanofluids with carbon tubes promoted heat conductivity, followed by exfoliated graphite and heat-treated nanofibers [12]. The precipitation of particles on a wall enhanced the heat transfer rate in polyalphaolefins-based nanofluids with exfoliated graphite fibers [13]. The thermophysical properties of polyalphaolefins-based nanofluids containing Al$_2$O$_3$ nanoparticles were dependent on particle volume fraction, particle aggregation, and dispersion [14].

The non-Newtonian fluids mentioned above involved Oldroyd-B, Jeffrey, and Maxwell fluids. The constitutive equations of these three non-Newtonian fluids can account for elasticity; hence, they are suited to model viscoelastic fluid but cannot account for the shear-thinning property of fluid. The constitutive equations of Jeffrey and Maxwell fluids are linear, and they can only be used to describe some simple flows. In practical applications, non-Newtonian fluid with both viscoelastic and shear-thinning characteristics is also common. To describe both characteristics, the constitutive equation of Giesekus fluid can be used. Hence, Giesekus fluid has attracted wide attention. However, a literature survey revealed that there is little research available on the friction factor and heat transfer of Giesekus-fluid-based nanofluids. Yang et al. [15] investigated the turbulent flow and heat transfer of Giesekus-fluid-based nanofluids in a channel and drew the conclusion that the viscoelasticity of Giesekus fluid resulted in drag reduction and the enhancement of convective heat transfer. Wang et al. [16] studied drag reduction in the gas–liquid two-phase turbulent flow of Giesekus fluids and indicated that it is better to use polymer drag-reducing agents with high concentrations in high shear flow. With the method of using Giesekus-fluid-based nanofluids, the effects of reducing friction and enhancing heat transfer performance are dependent on the Reynolds number, Weissenberg number, particle volume concentration, viscosity ratio, and mobility parameter, and there is still a lack of research on this issue. In addition, in previous studies, the distribution of particle volume concentration is usually assumed to be uniform without taking particle convection, diffusion, coagulation, or breakage into account. In this work, therefore, a numerical simulation was conducted to investigate the effects of the Reynolds number, the Weissenberg number, rheological properties, and particle concentration on the friction factor and heat transfer performance of Giesekus-fluid-based Al$_2$O$_3$ nanofluids in a pipe flow while considering the effects of particle convection, diffusion, coagulation, and breakage.

The rest of this paper is organized as follows. The flow and equations of nanofluids and particle equations are introduced in Sections 2 and 3, respectively. The numerical method is given in Section 4. In Section 5, the numerical results are presented and discussed. Finally, conclusions are drawn in Section 6.

2. Flow and Equations of Nanofluids

The flow of Giesekus-fluid-based nanofluids in a pipe is shown in Figure 1. For the incompressible flow, the continuity and momentum equations of Giesekus-fluid-based nanofluids are [17]:

\[ \nabla \cdot \mathbf{u} = 0 \]  
\[ \rho_{nf} \left( \frac{\partial \mathbf{u}}{\partial t} + \mathbf{u} \cdot \nabla \mathbf{u} \right) = \nabla \cdot \mathbf{\sigma} \]  
\[ \mathbf{\sigma} = -p \mathbf{I} + 2 \mu_{nf} \mathbf{D} + \mathbf{\tau} \]
where $\nabla$ is the differential operator; $u$, $p$, and $\rho_{nf}$ are the velocity, pressure, and density of nanofluids, respectively; $\sigma$ is the total stress tensor; $I$ is the unit tensor; $\mu_{nf}$ is the solvent viscosity; $\tau$ is the stress tensor; and $D$ is the rate-of-deformation tensor:

$$D = \frac{[\nabla u + (\nabla u)^T]}{2}$$  \hfill (4)

![Figure 1. Flow in a pipe and cylindrical coordinate system.](image)

The constitutive equation of Giesekus fluid is:

$$\lambda \tau + \frac{\alpha \lambda \mu_p}{\mu_p} \tau \cdot \tau + \tau = 2\mu_p D$$  \hfill (5)

where $\lambda$ is the fluid relaxation time; $\mu_p$ is the contribution of the polymer to viscosity; $\alpha$ is the mobility parameter; and the symbol $\nabla$ is the upper-convected time derivative:

$$\nabla \tau \equiv \frac{\partial \tau}{\partial t} + u \cdot \nabla \tau - (\nabla u)^T \cdot \tau - \tau \nabla u$$  \hfill (6)

The density and viscosity of nanofluids in Equations (2) and (3) are [18]:

$$\rho_{nf} = (1 - \Phi)\rho_f + \Phi \rho_p, \quad \mu_{nf} = \mu_t(1 + 2.5\Phi + 6.2\Phi^2)$$  \hfill (7)

where $\Phi$ is the particle concentration and subscripts $f$ and $p$ denote fluid and particles, respectively.

The energy equation is:

$$\frac{\partial T}{\partial t} + u \cdot \nabla T = D_{nf} \nabla^2 T$$  \hfill (8)

where $T$ is the nanofluid temperature and $D_{nf}$ is the thermal diffusivity coefficient of nanofluids:

$$D_{nf} = \frac{k_{nf}}{(\rho C_p)_{nf}}$$  \hfill (9)

where heat capacitance $(\rho C_p)_{nf}$ and $k_{nf}$ are [19]:

$$k_{nf} = k_f \left[ \frac{(k_p + 2k_f) - 2\Phi(k_f - k_p)}{(k_p + 2k_f) + \Phi(k_f - k_p)} \right], \quad (\rho C_p)_{nf} = (1 - \Phi)(\rho C_p)_f + \Phi(\rho C_p)_p$$  \hfill (10)

where $k$ is the thermal conductivity.

### 3. Equations of Particles

Particle concentration $\Phi$ in Equations (7) and (10) should be determined before solving Equations (1)–(6). The diffusion, convection, coagulation, and breakage of nanoparticles leads to a nonuniform distribution of $\Phi$ in the flow process; hence, it is necessary to solve the equation of particle concentration.
3.1. Dynamics Equation for Nanoparticles

Considering the convection, diffusion, coagulation, and breakage of nanoparticles, the equation of particle volume can be given as follows under a steady condition:

$$\frac{\partial n(v)}{\partial x_j} - \frac{\partial}{\partial x_j} \left[ D_v \frac{\partial n(v)}{\partial x_j} \right] = \frac{1}{2} \int_0^\infty \int_0^\infty \beta(v_1, v - v_1) n(v_1) n(v - v_1) dv_1 dv + \int_0^\infty \int_0^\infty \beta(v_1, v - v_1) n'(v_1) n'(v - v_1) dv_1 dv$$

$$- \int_0^\infty \beta(v_1, v) n(v) n(v_1) dv_1 + \int_0^\infty a(v_1) b(v, v_1) n(v_1) dv_1 - a(v) n(v)$$  \hspace{1cm} (11)

where $u_j$ is the nanofluids’ velocity; the subscript $j$ indicates summation; $n(v)$ is the distribution function of particle volume; $D_v = k_B T/3\pi \mu_{nf} d_p$ is the diffusion coefficient of particles with $k_B$ being the Boltzmann constant, $\mu_{nf}$ the viscosity, and $d_p$ the particle diameter; $\beta(v, v_1)$ is the coagulation kernel for two particles of volume $v$ and $v_1$; $\alpha(v)$ is the breakage kernel expressing the breakage frequency of particle $v$; and $b(v \mid v_1)$ is the breakage distribution function.

3.2. Moment Equation of Nanoparticles

Multiplying Equation (11) with $v^k$ and then integrating over $v$ yields:

$$\frac{\partial n_M^k}{\partial x_j} - \frac{\partial}{\partial x_j} \left( D_v \frac{\partial n_M^k}{\partial x_j} \right) = \frac{1}{2} \int_0^\infty \int_0^\infty [(v + v_1)^k - v^k - v_1^k] \beta(v, v_1) n(v_1) dv_1 dv + \int_0^\infty v^k a(v_1) b(v \mid v_1) n(v_1) dv_1 dv - \int_0^\infty v^k a(v) n(v) dv$$

where moment $M_k$ is:

$$M_k = \int_0^\infty v^k n(v) dv$$  \hspace{1cm} (12)

Taking $k = 0$ and 1 yields:

$$M_0 = \int_0^\infty n(v) dv = N, \quad M_1 = \int_0^\infty vn(v) dv = V$$  \hspace{1cm} (13)

where $M_0$ and $M_1$ are the total particle number and particle volume, respectively. Based on Equation (14), $\Phi$ can be calculated.

3.3. Particle Coagulation and Breakage

The coagulation kernel in Equation (12) is [20]:

$$\beta = B \left( \frac{1}{v^{1/3}} + \frac{1}{v_1^{1/3}} \right) (v^{1/3} + v_1^{1/3})$$

where $B = 2k_B T/\mu_{nf}$ with $k_B$ being the Boltzmann constant, $T$ the fluid temperature, and $\mu_{nf}$ the nanofluids’ viscosity.

The particle breakage function is composed of breakage kernel $\alpha(v)$ and breakage distribution function $b(v \mid v_1)$. The breakage kernel $\alpha(v)$ is [21]:

$$\alpha(v) = k_B \left( \frac{\nu_{nf}}{\tau^*} \right)^q v_{p1}^{1/3} \left( \frac{d_c(v)}{d_p} \right)^{3/D_f}$$

where $\nu_{nf}$ is the nanofluids’ viscosity; $G$ is the shear rate of flow; $\tau^*$ is characteristic shear stress and is a strength measure of the coagulated particles; $q$, $v_{p1}$, and $d_p$ are constants dependent on $\Phi$; $d_c$ is particle collision diameter and dependent on the number of primary particles; and $D_f$ is the fractal dimension of particles ($D_f = 3$ for spherical particles).
The breakage distribution function, \( b(v|v_1) \), is [22]:

\[
b(v|v_1) = \begin{cases} 2 & \text{if } v_1 = 2v \\ 0 & \text{otherwise} \end{cases}
\]  

Replacing the second term on the right-hand side of Equation (12) with Equation (17) yields:

\[
\int_0^\infty \int_0^\infty a(v_1)b(v|v_1)n(v_1)dv_1dv = \int_0^\infty \left[ \int_0^\infty b(v|v_1)dv \right]a(v_1)n(v_1)dv_1 = \int_0^\infty 2^{1-k}v_1^k a(v_1)n(v_1)dv_1
\]  

3.4. Taylor Series Expansion Moment Method

The Taylor series expansion technique [23,24] is used to solve moment equations. The equations of zero-, first-, and second-order moment can be given by substituting Equations (15)–(18) into Equation (12):

\[
\frac{\partial u_j M_0}{\partial x_j} - \frac{\partial}{\partial x_j}(D_p \frac{\partial M_0}{\partial x_j}) = \frac{B_2(-151M_1^4 + 2M_2^2M_0^2 - 13M_2M_1^2M_0)M_0^2}{81M_1^4}
\]  

\[
\frac{\partial u_j M_1}{\partial x_j} - \frac{\partial}{\partial x_j}(D_p \frac{\partial M_1}{\partial x_j}) = 0
\]  

\[
\frac{\partial u_j M_2}{\partial x_j} - \frac{\partial}{\partial x_j}(D_p \frac{\partial M_2}{\partial x_j}) = \frac{2B_2(2M_2^2M_0^2 - 13M_2M_1^2M_0 - 151M_1^4)}{81M_1^4}
\]

4. Numerical Method

4.1. Steps of Numerical Simulation

The numerical simulation included the following steps: (1) solving Equations (1)–(7) with \( \Phi = 0 \) to get \( u, p, \text{ and } \tau \); (2) solving Equations (11)–(21) to get \( n \) and \( \Phi \); (3) substituting \( \Phi \) into Equations (7), (9), and (10) to get \( \rho_{nf}, \mu_{nf}, D_{nf}, k_t, \text{ and } (\rho C_p)_{nf} \); (4) substituting \( \Phi, \rho_{nf}, \mu_{nf}, D_{nf}, k_t, \text{ and } (\rho C_p)_{nf} \) into Equations (1)–(8) to get \( u, p, \tau \), and \( T \); (5) turning to Step (2) based on the new values of \( u, p, \text{ and } \tau \) if necessary; (6) calculating the Fanning friction factor \( C_f \) and Nusselt number \( Nu \):

\[
C_f = \frac{\Delta p}{4\rho_{nf}(L/D)(u_{av}^2/2)}, \quad Nu = \frac{hD}{k_{nf}}
\]

where \( u_{av} \) and \( \Delta p \) are the mean velocity and pressure drop of the fluid, respectively, and \( h \) is the heat transfer coefficient; \( L \) and \( D \) are shown in Figure 1.

4.2. Numerical Method and Boundary Condition

The finite-volume method was used to solve Equations (2), (5), (8), and (19)–(21). The SIMPLE scheme was employed to handle the term of velocity–pressure coupling, and the power-law scheme was used to handle the convection term. The discretized equations were solved using a staggered mesh system and an alternating direction implicit method. The mesh size was uniform along \( z \) and \( \theta \) directions, while it was refined in \( r \) direction. On the wall, the velocity, zero-, first-, and second-order moment were zero; the heat flux was constant. The initial distributions of zero-, first-, and second-order moment and temperature were uniform.

4.3. Parameters

Giesekus fluid has both viscoelasticity and shear-thinning characteristics, and Al_2O_3 nanoparticles have the features of high energy density and thermal conductivity, safety, and low cost. Therefore, the Giesekus fluid and Al_2O_3 nanoparticles were selected as the...
The Reynolds number was defined as \( \text{Re} = \frac{\rho u D}{\mu} \).

Values of the heat flux were constant. The initial distributions of zero-, first-, and second-order moment and temperature were uniform.

The Giesekus fluid and \( \text{Al}_2\text{O}_3 \) nanoparticles were selected as the base fluid and disperse phase, respectively, in the present study. The parameters used in the numerical simulation were: \( \rho = 990 \text{ kg/m}^3 \), \( \rho_p = 3970 \text{ kg/m}^3 \), \( k_i = 0.65 \text{ W/m-K} \), \( k_p = 40 \text{ W/m-K} \), \( C_{pf} = 4.15 \text{ kJ/kg-K} \), \( C_{pp} = 0.765 \text{ kJ/kg-K} \), and \( k_b = 1.38 \times 10^{-23} \text{ J/K} \). The Reynolds number was defined as \( \text{Re} = \frac{\rho u D}{\mu} \).

4.4. Validation

The flow field was divided into \( 128(\theta) \times 32(z) \times 256(r) = 1,048,576 \) grids, and a test of independence for the grid size was performed, as shown in Table 1. The convergence criterion was that all the residual errors were less than \( 10^{-4} \).

To validate the numerical model used in the present simulation, the present numerical result of the axial velocity profile along the radial direction in the pipe flow of Giesekus fluid was compared with the result given by Vachagina et al. [25], as shown in Figure 2, where \( u_z \) is the ratio of local velocity to average velocity and the corresponding parameters are: \( Wi = 4.29 \) and \( \lambda = 84.25 \text{ s}^{-1} \). The present result of the relationship between the Nusselt number and the heat flux. As can be seen from Figures 2 and 3, our results were in agreement with previous results.

5. Results and Discussion
5.1. Friction Factor
The Fanning friction factor \(C_f\), as shown in Equation (22), was used to express the shear stress exacting on the flow by the wall.

5.1.1. Effect of Weissenberg Number
The relationship between the relative friction factor, \(C_f/C_{fNew}\), and the modified Weissenberg number, \(Wi^*\), for different particle concentrations, \(\Phi\), is shown in Figure 4, where the results [27] for pure Giesekus fluid are also given for comparison. The parameters in Figure 4 are: \(C_{fNew}\) is the friction factor for Newtonian fluid; \(Wi^* = 2Wi_{10}/(Re_0 L)\), where \(Wi_{10} = \lambda u_s^2/v_0\) (\(\lambda\) is relaxation time, \(u_s\) is friction velocity, and \(v_0\) is zero shear-rate kinematic viscosity) is zero shear-rate friction \(Wi\); \(Re_0 = D u_b/v_0\) (\(D\) is pipe diameter and \(u_b\) is bulk average velocity), \(L\) is the maximum extensibility parameter of polymer molecules; \(\beta_0 = \mu_s/\mu_0 = \mu_s/(\mu_s + \mu_p)\), where \(\mu_s\) is solvent viscosity, \(\mu_0\) is zero shear-rate viscosity, and \(\mu_p\) is viscosity from polymer contributions; and \(\alpha\) is a mobility parameter.

Figure 4. Friction factor vs. modified Weissenberg number for different particle concentrations (\(\beta_0 = 0.2, Re = 2.5, \alpha = 0.2\)). ––: \(\Phi = 0\%\) (Giesekus fluid) [27]; ––: \(\Phi = 0\%\) (Giesekus fluid); ––: \(\Phi = 0.5\%\); ––: \(\Phi = 1.0\%\); ––: \(\Phi = 2.0\%\); and ––: \(\Phi = 3.0\%\).
From Figure 4, we can see that $C_f/C_{f\text{New}}$ is always larger than 1, i.e., the $C_f$ of Giesekus-fluid-based nanofluids is larger than that of Newtonian fluid. $C_f/C_{f\text{New}} = 1$ when $Wi^* = 0$ because $Wi^* = 2Wi_{\text{el}}/(Re_{\text{el}}L)$ is the ratio of elastic to inertial force; $Wi^* = 0$ for Newtonian fluid. As $Wi^*$ increases, $C_f/C_{f\text{New}}$ increases rapidly when $0 < Wi^* < 0.5$ and slowly when $0.5 < Wi^* < 1$, and then it decreases slowly when $1 < Wi^* < 7$. $Wi$ is also the ratio of the first normal stress difference (FNSD) to shear stress. When $0 < Wi^* < 1$, the increase in $Wi^*$ means an increase in FNSD, so as to produce additional extension resistance and result in an increase in $C_f$. When $1 < Wi^* < 7$, the effect of the increase in FNSD is weakened; meanwhile, the effect of shear-thinning is increased, resulting in the decrease in $C_f$. Friction is the result of the combined action of various forces exacting on fluid. Therefore, there exists a maximum $C_f$ for certain rheological and physical properties of nanofluids and certain flow conditions.

5.1.2. Effects of Particle Concentration and Viscosity Ratio

In Figure 4, $C_f/C_{f\text{New}}$ increases with increasing $\Phi$. The nanoparticles in Giesekus fluid are responsible for energy absorption, leading to a large $C_f$. In addition, nanofluids’ viscosity, $\mu_{nf}$, is proportional to $\Phi$, as shown in Equation (7). $\mu_{nf}$ increases with increasing $\Phi$, intensifying the viscous sublayer and resulting in an increase in $C_f$. As $\Phi$ increases, the increase in $C_f/C_{f\text{New}}$ is large when $0 < \Phi < 0.5\%$ but small when $0.5\% < \Phi < 3.0\%$ because the variation in $\Phi$ has little impact on the viscous sublayer in this range of $\Phi$, showing that the effect of particle concentration on $C_f$ is nonlinear. In previous studies, there were different conclusions on the impact of nanoparticles in Newtonian-fluid-based nanofluids on $C_f$; most conclusions are that nanoparticles lead to an increase in $C_f$ (e.g., [28–31]). The results in Figure 4 show that nanoparticles in Giesekus-fluid-based nanofluids also lead to an increase in $C_f$.

Figure 5 shows the relationship between $C_f/C_{f\text{New}}$ and $Wi^*$ for different viscosity ratios, $\beta_0$. $\beta_0 = 0$ and 1 corresponds to pure polymer and Newtonian fluid because $\beta_0 = \mu_\text{nf}/(\mu_\text{f} + \mu_\text{p})$. We can see that $C_f/C_{f\text{New}} = 1$ for Newtonian fluid ($\beta_0 = 1$). As $Wi^*$ increases, $C_f/C_{f\text{New}}$ increases rapidly when $0 < Wi^* < 2$ and slowly when $2 < Wi^* < 7$ for the pure polymer ($\beta_0 = 0$), showing that $C_f$ is directly proportional to $Wi^*$ in the absence of solvent viscosity $\mu_s$. However, $C_f/C_{f\text{New}}$ first increases and then gradually decreases with the increase in $Wi^*$ when $0 < \beta_0 < 1$. Therefore, the changing trend of $C_f$ with $Wi^*$ depends on $\beta_0$. In addition, $C_f/C_{f\text{New}}$ increases with decreasing $\beta_0$, i.e., a large $\beta_0$ should be selected in order to reduce $C_f$.

- $\beta_0 = 0.2$.
5.1.3. Effects of Reynolds Number and Mobility Parameter

The Reynolds number represents the ratio of fluid inertia to viscosity, and its value represents the relative importance of the two. The range in Reynolds numbers in this paper was 0.5–500 because this can more fully reflect the situations of inertia or viscosity dominance. The relationship between $C_f/C_{f\text{New}}$ and $Wi^*$ for different $Re$ is shown in Figure 6, where $C_f/C_{f\text{New}}$ is reduced with increasing $Re$, but the relationship between the reducing rate of $C_f/C_{f\text{New}}$ and the increasing rate of $Re$ is nonlinear, i.e., the change rate for $C_f/C_{f\text{New}}$ is almost the same as the small change rate for $Re$ when $0.5 < Re < 1$, and there is a large change rate when $100 < Re < 500$. $C_f$ is proportional to viscosity and shear rate, and $Re$ is the ratio of inertia to viscosity. At a small $Re$, the function of viscosity is large, and the shear rate is large in most regions of flow, so there is a large $C_f$. At a small $Re$, the flow is sensitive to changes in $Re$, so $C_f$ is also sensitive to changes in $Re$. At a large $Re$, the inertial force is dominant against the viscous forces with increasing $Re$, so $C_f$ is less sensitive to changes in $Re$.

![Figure 6. Friction factor vs. modified Weissenberg number for different Reynolds numbers ($β_0 = 0.2$, $ϕ = 1.0\%$, $α = 0.2$).](image1)

Figure 6. Friction factor vs. modified Weissenberg number for different Reynolds numbers ($β_0 = 0.2$, $ϕ = 1.0\%$, $α = 0.2$). $-$: $Re = 500$; $-$: $Re = 100$; $-$: $Re = 10$; $-$: $Re = 2.5$; $-$: $Re = 1$; and $-$: $Re = 0.5$.

Figure 7 shows the relationship between $C_f/C_{f\text{New}}$ and $Wi^*$ for different mobility parameters, $α$; the degree of shear-thinning is proportional to $α$. Increasing $α$ leads to a decrease in $C_f/C_{f\text{New}}$ due to an increase in the shear-thinning effect. $C_f/C_{f\text{New}}$ is smaller for Giesekus-fluid-based nanofluids than for Oldroyd-B-based nanofluids ($α = 0$) under the same conditions. For a definite $α$ and larger $Wi^*$, the change in $C_f/C_{f\text{New}}$ becomes unobvious and $C_f/C_{f\text{New}}$ approaches asymptotic values. Despite the shear-thinning effect, $C_f/C_{f\text{New}}$ is still larger than 1 because there exists a polymer contribution, $μ_p$, to viscosity.

5.2. Heat Transfer

In order to understand the heat transfer performance of Giesekus-fluid-based nanofluids, we explored the impacts of Wi, Φ, β0, Re, and a on Nu, which is shown in Equation (22).

5.2.1. Effect of Weissenberg Number

The relationship between Nu and Wi for different Φ is shown in Figure 8, where the results [32] for pure Giesekus fluid are also given. Nu is at its minimum when Wi = 0 for Φ = 0, i.e., the heat transfer effect of Giesekus fluid is better than that of Newtonian fluid. As Wi increases, Nu increases rapidly when 0 < Wi < 2 and slowly when 2 < Wi < 8. For a definite Φ and larger Wi, Nu approaches asymptotic values, indicating that the fluid elasticity has little impact on heat transfer when Wi exceeds a certain value.

Figure 8. Nusselt number vs. Weissenberg number for different viscosity ratios (β0 = 0.2, Re = 2.5, α = 0.2). —: Φ = 0% (Giesekus fluid); —: Φ = 0% (Giesekus fluid); —: Φ = 0.5%; —: Φ = 0.2%; Φ = 1.0%; —: Φ = 2.0%; and —: Φ = 3.0%.

5.2.2. Effects of Particle Concentration and Viscosity Ratio

In Figure 8, the Nu for Φ ≠ 0 is larger than that for Φ = 0, indicating that adding nanoparticles into fluid can improve heat transfer. An increase in Φ usually leads to an increase in viscosity, as shown in Equation (7), and intensifies the viscous sublayer, which causes a decrease in heat transfer. However, the thermal conductivity of nanofluids is higher than that of pure fluid when adding nanoparticles with high thermal conductivity into fluid, which enhances the heat transfer effect. Therefore, the results in Figure 8 imply that the impact of thermal conductivity enhancement overcomes the impact of viscosity increase, which is consistent with previous results, e.g., [33]. Nu increases with increasing Φ because the interaction between particles is weak at a small Φ, meaning a weak heat transfer. At a large Φ, both frequent particle interaction and movement disturb the flow and enhance heat transfer. The increasing rate of Nu decreases with increasing Φ because the increase in viscosity is far greater than the increase in thermal conductivity at a large Φ. In addition, the nanoparticles with high Φ are easier to coagulate, resulting in a reduction in particle numbers, thereby affecting heat transfer performance.

Figure 9 shows the relationship between Nu and Wi for different viscosity ratios, β0. The Nu for β0 < 1 is larger than that for β0 = 1, i.e., the heat transfer performance of Giesekus-fluid-based nanofluids was better than that of Newtonian-fluid-based nanofluids, which is in agreement with previous conclusions that viscoelastic fluid can enhance heat transfer rates compared to Newtonian fluids, e.g., [34]. Nu decreases with increasing β0, and the reducing rate was almost the same when 0 < β0 < 1, showing the enhancement of heat transfer depends linearly on the viscosity ratio.
5.2.3. Effects of Reynolds Number and Mobility Parameters

The relationship between \( \text{Nu} \) and \( \text{Wi} \) for different \( \Phi \) is shown in Figure 10, where \( \text{Nu} \) increases with increasing \( \text{Re} \). The relationship between the growth rate of \( \text{Nu} \) and increasing rate of \( \text{Re} \) was nonlinear. As the flow was laminar in the range of \( \text{Re} \) in this paper, there are two reasons for why \( \text{Nu} \) was proportional to \( \text{Re} \): (1) the laminar sublayer becomes thinner and shear stress subsequently increases with increasing \( \text{Re} \); (2) more heat is carried by a faster moving fluid than a slower one.

![Graph: Nusselt number vs. Weissenberg number for different viscosity ratios](image.png)

**Figure 9.** Nusselt number vs. Weissenberg number for different viscosity ratios (\( \Phi = 1.0\% \), \( \text{Re} = 2.5 \), \( \alpha = 0.2 \)). \( \bullet \) : \( \beta_0 = 1.0 \); \( \bullet \) : \( \beta_0 = 0.9 \); \( \bullet \) : \( \beta_0 = 0.3 \); \( \bullet \) : \( \beta_0 = 0.2 \); \( \bullet \) : \( \beta_0 = 0.1 \); and \( \bullet \) : \( \beta_0 = 0 \).

5.2.3. Effects of Reynolds Number and Mobility Parameters

The relationship between \( \text{Nu} \) and \( \text{Wi} \) for different \( \text{Re} \) is shown in Figure 10, where \( \text{Nu} \) increases with increasing \( \text{Re} \). The relationship between the growth rate of \( \text{Nu} \) and increasing rate of \( \text{Re} \) was nonlinear. As the flow was laminar in the range of \( \text{Re} \) in this paper, there are two reasons for why \( \text{Nu} \) was proportional to \( \text{Re} \): (1) the laminar sublayer becomes thinner and shear stress subsequently increases with increasing \( \text{Re} \); (2) more heat is carried by a faster moving fluid than a slower one.

![Graph: Nusselt number vs. Weissenberg number for different Reynolds numbers](image.png)

**Figure 10.** Nusselt number vs. Weissenberg number for different Reynolds numbers (\( \beta_0 = 0.2 \), \( \Phi = 1.0\% \), \( \alpha = 0.2 \)). \( \bullet \) : \( \text{Re} = 0.5 \); \( \bullet \) : \( \text{Re} = 1 \); \( \bullet \) : \( \text{Re} = 2.5 \); \( \bullet \) : \( \text{Re} = 10 \); \( \bullet \) : \( \text{Re} = 100 \); and \( \bullet \) : \( \text{Re} = 500 \).

Figure 11 shows the relationship between \( \text{Nu} \) and \( \text{Wi} \) for different \( \alpha \). \( \text{Nu} \) increases with the increase in \( \alpha \), and the growth rate of \( \text{Nu} \) is almost the same when \( 0 < \alpha < 0.5 \), showing the increase in heat transfer depends linearly on \( \alpha \). The larger \( \alpha \) is, the more obvious the shear-thinning effect is and the thinner the viscous sublayer is, leading to increases in heat transfer. In Equation (5), \( \alpha = 0 \) corresponds to Oldroyd-B fluid; therefore, the heat transfer performance of Giesekus-fluid-based nanofluids is better than that of Oldroyd-B-based nanofluids.
5.3. Performance Evaluation Criterion

As shown above, the heat transfer performance of Giesekus-fluid-based nanofluids is better than that of Giesekus fluid, while the friction factor in the former is larger than that in the latter. Therefore, we need to balance the increase in heat transfer and enhancement of consumed power. An energy performance evaluation criterion (PEC) was employed to express the ratio of heat flow rate to required consumed power [35]:

$$\text{PEC} = \frac{(T_{\text{out}} - T_{\text{in}}) \int_{-D/2}^{D/2} 2\pi r u_r (\rho C_p)_{nf} \, dr}{\Delta P \int_{-D/2}^{D/2} 2\pi r u_r \, dr}$$

(23)

where $T_{\text{in}}$ and $T_{\text{out}}$ are the temperatures at the inlet and outlet of the pipe, respectively.

5.3.1. Effects of Various Factors on the PEC

The ratio of PEC for Giesekus-fluid-based nanofluids (PEC$_{nf}$) to that for Giesekus fluid (PEC$_{f}$) is expressed as PEC$_{nf}$/PEC$_{f}$. Figures 12–15 show PEC$_{nf}$/PEC$_{f}$ as a function of Wi for different $\Phi$, $\beta_0$, Re, and $\alpha$, respectively. At a small Wi ($Wi < 3–6$), the difference in $C_l/C_{l\text{New}}$ is larger than that in Nu between Giesekus-fluid-based nanofluids and Giesekus fluid; hence PEC$_{nf}$/PEC$_{f}$ is less than 1. On the contrary, PEC$_{nf}$/PEC$_{f}$ is larger than 1 at a large Wi because the difference in Nu is larger than that in $C_l/C_{l\text{New}}$. PEC$_{nf}$/PEC$_{f}$ increases with increasing Wi, $\Phi$, Re, and $\alpha$, and with decreasing $\beta_0$. Therefore, it is more effective to use nanofluids at a large Wi, $\Phi$, Re, and $\alpha$, but small $\beta_0$.

![Figure 11. Nusselt number vs. Weissenberg number for different mobility parameters (Re = 2.5, $\Phi$ = 1.0%, $\beta_0$ = 0.2).](image)

![Figure 12. PEC$_{nf}$/PEC$_{f}$ vs. Weissenberg number for different particle concentrations ($\beta_0$ = 0.2, Re = 2.5, $\alpha$ = 0.2).](image)
5.3.2. Correlation Model

In Figures 12–15, PEC_{nf}/PEC_{f} is proportional to Wi, Φ, Re, and α, but inversely proportional to β_0. In order to describe the impact of related parameters on PEC_{nf}/PEC_{f}, we built a correlation model relating PEC_{nf}/PEC_{f} to related parameters. Firstly, related parameters were combined into a dimensionless parameter:

\[ ξ = \frac{\text{Wi} Φ \text{Re} }{β_0} \]  \hspace{1cm} (24)  

We established a relationship between PEC_{nf}/PEC_{f} and ξ based on formula (24) and numerical data in Figures 12–15 as:

\[ \text{PEC}_{nf}/\text{PEC}_f = -0.17632e^{(ξ^2/171.88918)} + 1.12805 \]  \hspace{1cm} (25)
Figure 16 shows the numerical data in Figures 12–15 and formula (25) on a fitted curve.

6. Conclusions

The friction factor and heat transfer of Giesekus-fluid-based nanofluids in a pipe flow were investigated in order to understand the function of non-Newtonian-fluid-based nanofluids as a heat transfer medium. The impacts of $\text{Wi}$, $\Phi$, $\beta_0$, $\text{Re}$, and $\alpha$ on $C_t/C_{fNew}$, $\text{Nu}$, and $\frac{\text{PEC}_{nf}}{\text{PEC}_f}$ were discussed. The main conclusions are summarized as follows:

1. $C_t/C_{fNew}$ is larger for Giesekus-fluid-based nanofluids than for Newtonian fluid, and there exists a maximum $C_t/C_{fNew}$ under certain rheological and physical properties of nanofluids and flow conditions. As $\text{Wi}$ increases, $C_t/C_{fNew}$ first increases and then decreases. Nanoparticles in Giesekus-fluid-based nanofluids lead to an increase in $C_t/C_{fNew}$. An increase in $\Phi$ results in an increase in $C_t/C_{fNew}$, and the effect of $\Phi$ on $C_t/C_{fNew}$ is nonlinear. $C_t/C_{fNew}$ is proportional to $\text{Wi}$ in the absence of solvent viscosity, and the changing trend of $C_t/C_{fNew}$ with $\text{Wi}$ depends on $\beta_0$. A large $\beta_0$ should be selected in order to reduce friction factor. $C_t/C_{fNew}$ is reduced with increasing $\text{Re}$, but the relationship between the reducing rate of $C_t/C_{fNew}$ and increasing rate of $\text{Re}$ is nonlinear. Increasing $\alpha$ leads to a decrease in $C_t/C_{fNew}$, and Giesekus-fluid-based nanofluids have a smaller $C_t/C_{fNew}$ than Oldroyd-B-based nanofluids.

2. As $\text{Wi}$ increases, $\text{Nu}$ increases rapidly when $0 < \text{Wi} < 2$ and slowly when $2 < \text{Wi} < 8$, and fluid elasticity has little effect on $\text{Nu}$ when $\text{Wi}$ exceeds a certain value. Adding nanoparticles into fluid can enhance heat transfer. $\text{Nu}$ increases with increasing $\Phi$, and the increasing rate of $\text{Nu}$ decreases with the increase in $\Phi$. Giesekus-fluid-based nanofluids have a better heat transfer effect than Newtonian-fluid-based nanofluids. $\text{Nu}$ decreases with increasing $\beta_0$, and the enhancement of $\text{Nu}$ depends linearly on $\beta_0$. $\text{Nu}$ increases with increasing $\text{Re}$, and the relationship between the growth rate of $\text{Nu}$ and increase rate of $\text{Re}$ is nonlinear. $\text{Nu}$ increases with an increase in $\alpha$, and the enhancement of $\text{Nu}$ depends linearly on $\alpha$.

3. $\frac{\text{PEC}_{nf}}{\text{PEC}_f}$ increases with increasing $\text{Wi}$, $\Phi$, $\text{Re}$, and $\alpha$, and with decreasing $\beta_0$. It is more effective to use nanofluids at a large $\text{Wi}$, $\Phi$, $\text{Re}$, and $\alpha$, but small $\beta_0$. Finally, the formula of $\frac{\text{PEC}_{nf}}{\text{PEC}_f}$ as a function of $\text{Wi}$, $\Phi$, $\beta_0$, $\text{Re}$, and $\alpha$ was derived based on numerical data.
