Controllability of a Class of Heterogeneous Networked Systems

Abhijith Ajayakumar † and Raju K. George * †

Abstract: This paper examines the controllability of a class of heterogeneous networked systems where the nodes are linear time-invariant systems (LTI), and the network topology is triangularizable. The literature contains necessary and sufficient conditions for the controllability of such systems where the control input matrices are identical in each node. Here, we extend this result to a class of heterogeneous systems where the control input matrices are distinct in each node. Additionally, we discuss the controllability of a more general system with triangular network topology and obtain necessary and sufficient conditions for controllability. Theoretical results are supplemented with numerical examples.

Keywords: controllability; heterogeneous dynamics; networked control systems

1. Introduction

The controllability of networked dynamical systems remains one of the most challenging problems in the field of control theory. The prevalence of networks of dynamical systems in numerous engineering and technology fields supports the rising emphasis placed on the controllability of networked systems [1–3]. In System and Control literature, there are different notions of controllability, including state controllability, structural controllability, etc. The classical idea of controllability, introduced by R. E. Kalman [4] in the 1960s, deals with the ability of a single high-dimensional system to steer itself from an arbitrary initial state to a desired final state, whereas, structural controllability, introduced by Lin [5] in 1974, attempts to obtain some numerical values for the parameters in system matrices describing the system’s dynamics so that it is controllable in the sense of Kalman. Using rank conditions, spectral features, graph-theoretic properties, etc., many authors have explored controllability criteria for such systems over the past few decades [6–13]. The traditional theory of control paved the way for an advanced approach applicable to complex networks with more than one interconnected dynamical system. With time, it was evident that modelling complicated real-life systems required large-scale networks, and the controllability of such systems became unavoidable [14–17].

Over the years, several approaches have been employed to study the controllability of a dynamical system. Zhou [18] studied the controllability and observability of networked systems having different dynamics in each subsystem. Based on the Popov–Belevitch–Hautus(PBH) test, he obtained some necessary and sufficient conditions for controllability which depended upon the dynamics of the subsystems and the network topology. Wang et al. [19] proposed a set of necessary conditions for the controllability of a homogeneous LTI networked system that required solving matrix equations. Additionally, conditions were derived that can be used to analyze the controllability of the networked system based on network topology, node dynamics, external control inputs, and inner interactions. In Wang L. et al. [19], the interactions between connected nodes are performed through high-dimensional inputs and outputs of the node dynamics. Later, Wang L. et al. [20] studied the controllability of homogeneous networked LTI systems having one-dimensional communication. They obtained a necessary and sufficient condition...
for the controllability of such systems along with some controllability results over specific network topologies, such as a chain, tree, star, etc. A relatively simple, less computational method for the controllability of homogeneous networked LTI systems was given by Hao et al. [21] in 2018 using spectral properties. Compared with Wang L. et al. [19], the conditions are easy to verify as they do not involve solving matrix equations. All these works discussed the controllability of a networked system with nodes having identical dynamics. However, in real-life situations, the individual nodes may not always have the same dynamics. Controllability of networked systems with heterogeneous dynamics poses a fascinating challenge as the intrinsic dynamics of individual nodes add to the complexity contributed by the network topology. Wang P. et al. [22] tried to extend the results obtained by Wang L. et al. [19] that were for homogeneous systems to heterogeneous systems. Some necessary conditions for controllability were obtained based on the network topology and the subsystem dynamics. Based on this work, Xiang et al. [23] derived necessary and sufficient conditions for controllability of a particular class of heterogeneous systems. Based on the results of Xiang et al. [23], Ajayakumar et al. [24] derived some necessary conditions for the controllability of heterogeneous systems. Using the idea of the determinant factor and the Smith normal form, a necessary and sufficient condition for controllability was derived by Kong et al. [25] for a general heterogeneous networked system. However, the result is difficult to verify as it involves significant computation. Ajayakumar et al. [26] extended the result of Hao et al. [21] that was for the controllability of homogeneous systems to a particular class of heterogeneous systems with identical control input matrices.

In this work, we extend the result in [26] to a class of heterogeneous networked systems, where the control input matrix is non-identical in each node. We also examine the controllability of a more general heterogeneous networked system over some specific network topologies. Necessary and sufficient conditions for the controllability of such systems are obtained. The rest of the paper is arranged as follows. Some preliminary information is given in Section 2. The controllability problem is formulated in Section 3. Section 4 presents the necessary and sufficient conditions for the controllability of the heterogeneous networked system formulated in Section 3. It also provides some controllability results over some specific topologies. Examples are provided to substantiate the derived results. Section 5 concludes the study and outlines the future scope of the research.

2. Preliminaries

In this paper, we use the following notations. I denotes the identity matrix and \( \{e_1, e_2, \ldots, e_n\} \) represents the canonical basis for \( \mathbb{R}^n \). Let \( \text{diag}\{a_1, a_2, \ldots, a_n\} \) denote diagonal matrix of order \( n \) with diagonal entries \( a_1, a_2, \ldots, a_n \), and \( \text{uppertriang}\{a_1, a_2, \ldots, a_n\} \) denotes an upper triangular matrix of the form

\[
\begin{bmatrix}
a_1 & * & * & \cdots & * \\
0 & a_2 & * & \cdots & * \\
0 & 0 & a_3 & \cdots & * \\
\vdots & \vdots & \vdots & \ddots & \vdots \\
0 & 0 & 0 & \cdots & a_n
\end{bmatrix}
\]

Let \( \sigma(A) \) denotes the eigen spectrum of a matrix \( A \). The following lemmas will be used in the subsequent sections of this paper.

**Lemma 1 ([27]).** Let \( A \) and \( B \) be similar matrices, that is, there exists a non-singular matrix \( P \), such that \( PBP^{-1} = A \). If \( v \) is a left eigenvector of \( A \) with respect to the eigenvalue \( \lambda \), then \( vP \) is an eigenvector of \( B \) with respect to the eigenvalue \( \lambda \).

**Lemma 2 ([28]).** Let \( A \otimes B \) denotes the Kronecker product of two matrices \( A \) and \( B \). We use the following properties of Kronecker product in this paper.

(i) \( (A \otimes B)(C \otimes D) = (AC \otimes BD) \).
Foundations 2023, 3

(iii) \((A \otimes B)^{-1} = A^{-1} \otimes B^{-1}\) if \(A\) and \(B\) are invertible.

(iv) \((A + B) \otimes C = A \otimes C + B \otimes C\).

(v) \(A \otimes B = 0\) if and only if \(A = 0\) or \(B = 0\).

Lemma 3 ([29]). A linear time-invariant control system characterized by the pair of matrices \((A, B)\) is controllable if, and only if, left eigenvectors of \(A\) are not orthogonal to columns of \(B\), i.e.,

\[ vA = \lambda v \implies \text{vB} \neq 0. \]

3. Model Formulation

Consider a heterogeneous networked linear time-invariant system with \(N\) nodes, where the \(i^{th}\) node is described by the following differential equation:

\[
\dot{x}_i(t) = A_i x_i(t) + \sum_{j=1}^{N} c_{ij} H x_j(t) + d_i B_i u_i(t), \quad i = 1, 2, \ldots, N
\]

where, \(x_i(t) \in \mathbb{R}^n\) is the state vector and \(u_i(t) \in \mathbb{R}^m\) is the external control vector. \(A_i\) is an \(n \times n\) matrix and \(B_i\) is an \(n \times m\) matrix called the state matrix and the control matrix of node \(i\), respectively.

\[
d_i = \begin{cases} 1, & \text{if node } i \text{ is under control} \\
0, & \text{otherwise} \end{cases}
\]

The connection strength between the nodes \(i\) and \(j\) is given by \(c_{ij} \in \mathbb{R}\). If there is a communication from node \(j\) to node \(i\), \(c_{ij} \neq 0\) and otherwise, \(c_{ij} = 0, i,j = 1, 2, \ldots, N\). The \(n \times n\) matrix \(H\) denotes the inner coupling matrix describing the interconnections among the states \(x_j, j = 1, 2, \ldots, N\) of the nodes.

The network topology and external input channels of the networked system (1), are given by the \(N \times N\) matrices

\[
C = [c_{ij}] \quad \text{and} \quad D = \text{diag}\{d_1, d_2, \ldots, d_N\}
\]

respectively. If we denote the state matrix and the total external control input of the networked system (1) by \(X = [x_1^T, \ldots, x_N^T]^T\) and \(U = [u_1^T, \ldots, u_N^T]^T\), respectively, using the Kronecker product notation, (1) can be reduced into the following compact form:

\[
\dot{X}(t) = FX(t) + GU(t)
\]

with,

\[
F = A + C \otimes H, \quad G = (D \otimes I)B
\]

where \(A = \text{blockdiag}\{A_1, A_2, \ldots, A_N\}\) and \(B = \text{blockdiag}\{B_1, B_2, \ldots, B_N\}\). If the inner coupling matrix is also different in each node, i.e., if the dynamics of the \(i^{th}\) node is given by

\[
\dot{x}_i(t) = A_i x_i(t) + \sum_{j=1}^{N} c_{ij} H x_j(t) + d_i B_i u_i(t), \quad i = 1, 2, \ldots, N
\]

the networked system can be reduced to the compact form (3), where

\[
F = \begin{bmatrix} A_1 + c_{11} H_1 & c_{12} H_1 & \cdots & c_{1N} H_1 \\ c_{21} H_2 & A_2 + c_{22} H_2 & \cdots & c_{2N} H_2 \\ \vdots & \vdots & \ddots & \vdots \\ c_{N1} H_N & c_{N2} H_N & \cdots & A_N + c_{NN} H_N \end{bmatrix}
\]

and \(G = (D \otimes I)B\).
4. Controllability Results in a General Network Topology

Ajayakumar et al. [26] studied the controllability of (3) when the network topology is triangularizable, and the system parameter matrices satisfy certain conditions. There the control input matrices were identical in each node. Here, we will extend this result to a system where each node has different control input matrices.

We find that there exists a non-singular matrix $T$, such that $TCT^{-1} = J$, where $J = \text{uppertriang}(\lambda_1,\ldots,\lambda_N)$ is the Jordan Canonical Form of $C$. Let $\sigma(A_1 + \lambda_i H) = \{\mu_1^i,\ldots,\mu_N^i\}$ denotes the set of eigenvalues of $A_1 + \lambda_i H$, $i = 1,\ldots,N$ and $\xi_{ij}^k$, $k = 1,\ldots,\gamma_{ij}$ be the left eigenvectors of $A_1 + \lambda_i H$ corresponding to $\mu_j^i$, $j = 1,\ldots,q_i$, $i = 1,\ldots,N$, where $\gamma_{ij} \geq 1$ is the geometric multiplicity of the eigenvalue $\mu_j^i$. We will make use of the following theorem.

**Theorem 1** ([26]). Let $T$ be the triangularizing matrix for the network topology matrix $C$ and suppose $T \otimes I$ commutes with $A$. Let $(\mu_j^i, \xi_{ij}^k)$ denotes the left eigenpair of $A_1 + \lambda_i H$. Then the following statements hold true.

(i) The eigenspectrum of $F$ is the union of eigenspectrum of $A_i + \lambda_i H$, where, $i = 1,2,\ldots,N$. That is,

$$\sigma(F) = \bigcup_{i=1}^N \sigma(A_i + \lambda_i H) = \{\mu_1^1,\ldots,\mu_N^1,\mu_1^2,\ldots,\mu_N^2,\ldots,\mu_1^N,\ldots,\mu_N^N\}$$

(ii) If $J$ is a diagonal matrix, then $\gamma_{ij}$ and $\mu_j^i$ are the left eigenvectors of $F$ corresponding to the eigenvalue $\mu_j^i$, $j = 1,\ldots,q_i$, $i = 1,\ldots,N$.

(iii) If $J$ contains a Jordan block of order $l \geq 2$ for some eigenvalue $\lambda_{ij}$ of $C$ with $\xi_{ij}^k H = 0$ for all $i = i_0, i_0 + 1,\ldots, i_0 + l - 1, j = 1,2,\ldots,q_i$, $k = 1,2,\ldots,\gamma_{ij}$, then $e_i T \otimes \xi_{ij}^k$, $k = 1,\ldots,\gamma_{ij}$ are the left eigenvectors of $F$ corresponding to the eigenvalue $\mu_j^i$, $i = 1,2,\ldots,N$, $j = 1,2,\ldots,q_i$.

With the aid of the above result, we can prove the following necessary and sufficient conditions for controllability of the networked system (3).

**Theorem 2.** Let $T$ be a non-singular matrix triangularizing matrix $C$ such that $T \otimes I$ commutes with $A$. If $J$ contains a Jordan block of order $l \geq 2$ corresponding to the eigenvalue $\lambda_{ij}$ of $C$ and $\xi_{ij}^k H = 0$ for all $i = i_0, i_0 + 1,\ldots, i_0 + l - 1, j = 1,2,\ldots,q_i$, $k = 1,2,\ldots,\gamma_{ij}$, then $e_i T \otimes \xi_{ij}^k$, $k = 1,\ldots,\gamma_{ij}$ are the left eigenvectors of $A_1 + \lambda_i H$ corresponding to the eigenvalues $\mu_j^i$, $i = 1,2,\ldots,N$, $j = 1,2,\ldots,q_i$. Then, the networked system (3) is controllable if, and only if,

(i) $e_i T D \neq 0$ for all $i = 1,\ldots,N$

(ii) For a fixed $i$, each left eigenvector $\xi$ of $A_1 + \lambda_i H$, $\xi B_j \neq 0$ for some $j \in \{1,2,\ldots,N\}$ with $[e_i T D]_j \neq 0$.

(iii) If matrices $A_{i_1} + \lambda_i H, A_{i_2} + \lambda_i H,\ldots,A_{i_p} + \lambda_i H (\lambda_i \in \sigma(C), k = 1,\ldots,p,$ where $p > 1$) have a common eigenvalue $\sigma$, then $(e_i T D \otimes \xi_{i_1}^1 B,\ldots,(e_i T D \otimes \xi_{i_p}^1 B,\ldots,(e_i T D \otimes \xi_{i_1}^2 B,\ldots,(e_i T D \otimes \xi_{i_p}^2 B,\ldots,(e_i T D \otimes \xi_{i_1}^p B,\ldots,(e_i T D \otimes \xi_{i_p}^p B$ are linearly independent vectors, where $\gamma_{ik} \geq 1$ is the geometric multiplicity of $\sigma$ for $A_{i_k} + \lambda_i H$ and $\xi_{i_k}^l$ $(l = 1,\ldots,\gamma_{ik})$ are the left eigenvectors of $A_{i_k} + \lambda_i H$ corresponding to $\sigma$, $i = 1,\ldots,p$.

**Proof.** (Necessary part) Fix $i$. Let $\xi$ be an arbitrary left eigenvector of $A_1 + \lambda_i H$. From Theorem 1, we find that $e_i T \otimes \xi$ is a left eigenvector of $F$. By Lemma 3, for the networked system (3) to be controllable, we must have

$$(e_i T \otimes \xi)(D \otimes I)B = (e_i T D \otimes \xi)B \neq 0$$

This implies that $e_i T D \neq 0$ and $\xi B_j \neq 0$ for some $j \in \{1,2,\ldots,N\}$ with $[e_i T D]_j \neq 0$. 

Now, suppose that the matrices $A_{i_1} + \lambda_{i_1} H, \ldots, A_{i_p} + \lambda_{i_p} H (\lambda_{i_k} \in \sigma(C), k = 1, \ldots, p, \text{ where } p > 1)$ have a common eigenvalue $\sigma$. Then the left eigenvectors of $F$ corresponding to $\sigma$ can be expressed as a linear combination in the form $\sum_{k=1}^{p} \sum_{l=1}^{\gamma_{ik}} a_{kl} (e_{i_1} T \otimes \tilde{\xi}_{ik}^l)$, where $a_{kl} \in \mathbb{R}(k = 1, \ldots, p, l = 1, \ldots, \gamma_{ik})$ are scalars, not all are zero and $\tilde{\xi}_{ik}^1, \ldots, \tilde{\xi}_{ik}^{\gamma_{ik}}$, are the corresponding eigenvectors of $A_{i_k} + \lambda_{i_k} H$.

This implies that either $e_{i}^T D \sigma$ does not hold true, when the networked system is uncontrollable, at least one condition in Theorem 1 does not hold. Suppose that $\sum_{l=1}^{\gamma_{i0}} a_{i0}^l (e_{i_0} T \otimes \tilde{\xi}_{i0}^l) = 0$ is some non-zero vector. Now $\sigma G = 0$ implies

$$\sum_{l=1}^{\gamma_{i0}} a_{i0}^l (e_{i_0} T \otimes \tilde{\xi}_{i0}^l) (D \otimes I) B = 0$$

This implies that either $e_{i_0} T = 0$ or $\sum_{l=1}^{\gamma_{i0}} a_{i0}^l (e_{i_0} T \otimes \tilde{\xi}_{i0}^l) B_j = 0$ for all $j \in \{1, 2, \ldots, N\}$ with $[e_{i} T]_j \neq 0$. Keep in mind that $\sum_{l=1}^{\gamma_{i0}} a_{i0}^l (e_{i_0} T \otimes \tilde{\xi}_{i0}^l)$ is a left eigenvector of $A_{i_0} + \lambda_{i_0} H$. Thus, if the networked system is uncontrollable, then either condition (i) or condition (ii) does not hold true.

Let $\tilde{\mu}$ be the common eigenvalue of the matrices $A_{i_1} + \lambda_{i_1} H, \ldots, A_{i_p} + \lambda_{i_p} H (\lambda_{i_k} \in \sigma(C), k = 1, \ldots, p, p > 1)$. Additionally, let the eigenvectors of $A_{i_k} + \lambda_{i_k} H$ corresponding to $\tilde{\mu}$ are $\tilde{\xi}_{ik}^1, \ldots, \tilde{\xi}_{ik}^{\gamma_{ik}}$, where $k = 1, \ldots, p$. Since $\sigma$ can be expressed in the form $\sum_{k=1}^{p} \sum_{l=1}^{\gamma_{ik}} a_{kl} (e_{i_k} T \otimes \tilde{\xi}_{ik}^l)$, where $a_{kl}^l (l = 1, \ldots, p)$ are some scalars, which are not all zero. Then, $\sigma G = 0$ implies that there exists a non-zero vector $\tilde{\xi}_{i0}^{1}, \ldots, \tilde{\xi}_{i0}^{\gamma_{i0}}, a_{i0}^1, \ldots, a_{i0}^{\gamma_{i0}, p}$, such that

$$\sum_{k=1}^{p} \sum_{l=1}^{\gamma_{ik}} a_{kl} (e_{i_k} T \otimes \tilde{\xi}_{ik}^l) (D \otimes I) B = 0$$

This implies that $(e_{i_0} T \otimes \tilde{\xi}_{i0}^1) B, \ldots, (e_{i_0} T \otimes \tilde{\xi}_{i0}^{\gamma_{i0}}) B, \ldots, (e_{i_p} T \otimes \tilde{\xi}_{i_p}^1) B, \ldots, (e_{i_p} T \otimes \tilde{\xi}_{i_p}^{\gamma_{i_p}}) B$ are linearly dependent. Thus, at least one condition in Theorem 2 does not hold true, when the networked system is uncontrollable. □
The following examples illustrate the result obtained in Theorem 2.

**Example 1.** Consider a heterogeneous networked system with three nodes with the following dynamics; the state matrices and control matrices of each node are given by,

\[
A_1 = \begin{bmatrix} 1 & 1 & 1 \\ 0 & 1 & 1 \\ 0 & 0 & 1 \end{bmatrix}, \quad A_2 = A_3 = \begin{bmatrix} 1 & 2 & 1 \\ 0 & 1 & 1 \\ 1 & 1 & 2 \end{bmatrix}, \quad B_1 = \begin{bmatrix} 1 \\ 0 \\ 1 \end{bmatrix}, \quad B_2 = \begin{bmatrix} 1 \\ -1 \end{bmatrix}, \quad B_3 = \begin{bmatrix} 1 \\ 1 \end{bmatrix} \quad (6)
\]

The network topology matrix, inner-coupling matrix, and the external control input matrix are, respectively,

\[
C = \begin{bmatrix} 0 & 0 & 1 \\ 0 & 1 & 1 \\ 0 & 0 & 0 \end{bmatrix}, \quad H = \begin{bmatrix} 1 & 1 & 0 \\ 1 & 1 & 1 \\ 0 & 0 & 0 \end{bmatrix}, \quad D = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 1 \end{bmatrix} \quad (7)
\]

Nodes \(\{v_1, v_2, v_3\}\) and \(\{u_1, u_2\}\) in Figure 1 represents the state nodes and the control nodes respectively. There exists a non-singular matrix \(T = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 0 & 1 \\ 0 & 1 & 1 \end{bmatrix}\), such that \(TCT^{-1} = \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 1 \end{bmatrix}\).

We have, \(\lambda_1 = 1, \lambda_2 = 1, \lambda_3 = -1\). Clearly, \(J\) contains a Jordan block of order 2 corresponding to 0. \(\xi_{11}^1 = [0 \ 0 \ 1]\) is the only left eigenvector of the matrix \(A_1 + \lambda_1H = A_1\) and \(\xi_{11}^2H = 0\). Additionally, \(T \otimes I\) commutes with \(A\). Then

(i) as \(TD = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 0 & 1 \\ 0 & 0 & 1 \end{bmatrix}\), \(e_iTD \neq 0\) for all \(i = 1, 2, 3\).

(ii) for \(A_1 + \lambda_1H = A_1 = \begin{bmatrix} 1 & 1 & 1 \\ 0 & 1 & 1 \\ 0 & 0 & 1 \end{bmatrix}\), the only left eigenvector is \(\xi_{11}^1 = [0 \ 0 \ 1]\). We have \([e_1TD]_1 \neq 0\) and \(\xi_{11}^1B_1 \neq 0\).

For the matrix \(A_2 + \lambda_2H = A_2 = \begin{bmatrix} 1 & 2 & 1 \\ 0 & 1 & 1 \\ 1 & 1 & 2 \end{bmatrix}\), the left eigenvectors are, respectively,

\(\xi_{21}^1 = [0.44062 \ 0.828911 \ 1]\), \(\xi_{22}^1 = [-0.72031 - 0.784805i - 0.914456 + 1.47641i 1]\)

and \(\xi_{23}^1 = [-0.72031 + 0.784805i - 0.914456 - 1.47641i 1]\). We have \([e_2TD]_3 \neq 0\) and \(\xi_{21}^1B_3, \xi_{22}^1B_3, \xi_{23}^1B_3 \neq 0\).

For the matrix \(A_3 + \lambda_3H = A_3 + H = \begin{bmatrix} 2 & 3 & 1 \\ 1 & 2 & 2 \\ 1 & 1 & 2 \end{bmatrix}\), the left eigenvectors are, respectively,

\(\xi_{31}^1 = [0.720551 \ 1.09001 \ 1]\), \(\xi_{32}^1 = [-0.0875483 - 0.34424i - 0.681369 + 0.450503i 1]\)

and \(\xi_{33}^1 = [-0.0875483 + 0.34424i - 0.681369 - 0.450503i 1]\). We have \([e_3TD]_3 \neq 0\) and \(\xi_{31}^1B_3, \xi_{32}^1B_3, \xi_{33}^1B_3 \neq 0\).

(iii) as the matrices \(A_1, A_2\) and \(A_3 + H\) do not have any common eigenvalues, third condition of Theorem 2 is satisfied.

Thus, all the conditions of Theorem 2 are satisfied and hence the system is controllable.
Then, by Theorem 2, the networked system is not controllable. From Figure 2, we can see that only
There exists a non-singular matrix
Additionally, $T^{-1}$
are, respectively,
Consider a heterogeneous networked system with 3 nodes with the following dynamics;
The state matrices and control matrices of each nodes are given by,

$$
A_1 = \begin{bmatrix} 0 & 0 & 0 \\ 0 & 1 & -2 \\ 0 & 0 & -1 \end{bmatrix}, \quad A_2 = A_3 = \begin{bmatrix} 0 & 1 & 1 \\ 2 & 1 & -1 \\ 0 & 2 & -1 \end{bmatrix}, \quad B_1 = \begin{bmatrix} 0 \\ 1 \\ 1 \end{bmatrix}, \quad B_2 = \begin{bmatrix} 0 \\ 1 \\ 1 \end{bmatrix}, \quad B_3 = \begin{bmatrix} 0 \\ 1 \\ 1 \end{bmatrix}
$$

(8)

The following examples illustrate the result as in (6) and (7).

Example 2. Consider a heterogeneous networked system with three nodes with the following
dynamics; the state matrices and control matrices of each nodes are given by,

The network topology matrix, inner-coupling matrix, and the external control input matrix
are, respectively,

$$
C = \begin{bmatrix} 1 & 1 & 1 \\ 0 & 0 & 1 \\ 0 & 1 & 0 \end{bmatrix}, \quad H = \begin{bmatrix} 1 & 1 & 0 \\ 0 & 1 & 1 \\ 0 & 1 & 1 \end{bmatrix}, \quad D = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix}
$$

(9)

There exists $T = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 1 \\ 0 & 1 & 0 \end{bmatrix}$, such that $TCT^{-1} = \begin{bmatrix} 1 & 1 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & -1 \end{bmatrix}$. The eigenvalues of $C$
are, $\lambda_1 = 1, \lambda_2 = 1$ and $\lambda_3 = -1$. Clearly, $I$ contains a Jordan block of order 2. Observe that
$\xi_{11}^{1} = \begin{bmatrix} 0 & 1 \\ 1 & -1 \end{bmatrix}$ is the only left eigenvector corresponding to the matrix $A_1 + H$ and $\xi_{11}^{1}H = 0$.

Additionally, $T \otimes I$ commutes with $A$. Here, as $TD = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix}$, we have $e_2 TD = e_3 TD = 0$.

Then, by Theorem 2, the networked system is not controllable. From Figure 2, we can see that only
node $v_1$ have an external control input. It is easy to observe, if either node $v_2$ or $v_3$ is supplied with a
control input, $e_i TD \neq 0$ for all $i = 1, 2, 3$. Suppose that node $v_2$ is supplied with an external control
input as shown in Figure 3. That is, $D = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 0 \end{bmatrix}$. Even then the networked system is not
controllable as $[e_1 TD]_1$ is the only non-zero entry in $e_1 TD$ and $\xi_{11}^{1}B_1 = 0$. If we could change the
control input matrix $B_1$ so that $\xi_{11}^{1}B_1 \neq 0$, we can make this uncontrollable system to a controllable
system. For example, consider $B_1 = \begin{bmatrix} 1 & 1 \\ 0 & 0 \end{bmatrix}$. Then,

(i) as $TD = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 1 & 0 \end{bmatrix}$, $e_i TD \neq 0$ for all $i = 1, 2, 3$. 

---

**Figure 1.** Controllable heterogeneous networked system with triangularizable network topology $C$ and node dynamics as in (6) and (7).
Thus all the conditions of Theorem 2 are satisfied and hence the system is controllable.

For $A_2 + H = \begin{bmatrix} 1 & 2 & 1 \\ 2 & 2 & 0 \\ 0 & 3 & 0 \end{bmatrix}$, the left eigenvectors are $\xi_{21}^{1} = \begin{bmatrix} -0.452737 + 1.15383i \\ -0.336813 - 1.0993i \\ 1 \end{bmatrix}$, and $\xi_{23}^{1} = \begin{bmatrix} -0.452737 - 1.15383i \\ -0.336813 + 1.0993i \\ 1 \end{bmatrix}$. We have $[e_1 TD]_2 \neq 0$ and $\xi_{21}^{1} B_2 \neq 0$.

and for the matrix $A_3 - H = \begin{bmatrix} -1 & 0 & 1 \\ 2 & 0 & -2 \\ 0 & 1 & -2 \end{bmatrix}$, the left eigenvectors are $\xi_{31}^{3} = \begin{bmatrix} 2 & 1 & 0 \end{bmatrix}$, $\xi_{32}^{3} = \begin{bmatrix} -0.25 + 0.661438i \\ -0.375 - 0.330719i \\ 1 \end{bmatrix}$, and $\xi_{33}^{3} = \begin{bmatrix} -0.25 - 0.661438i \\ -0.375 + 0.330719i \\ 1 \end{bmatrix}$. We have $[e_3 TD]_2 \neq 0$ and $\xi_{31}^{3} B_3, \xi_{32}^{3} B_2, \xi_{33}^{3} B_2 \neq 0$.

(iii) as the matrices $A_1 + H, A_2 + H$ and $A_3 - H$ do not have any common eigenvalues, third condition of Theorem 2 is satisfied.

Thus, all the conditions of Theorem 2 are satisfied and, hence, the system is controllable.

---

**Figure 2.** Uncontrollable heterogeneous networked system with triangularizable network topology $C$ and node dynamics, as in (8) and (9).

**Figure 3.** Controllable heterogeneous networked system with triangularizable network topology $C$ and node dynamics, as in (8) and (9).

Thus, with the help of conditions in Theorem 2 we can modify the system components in order to make an uncontrollable system controllable. Now, suppose that $(A_i + \lambda_i H, B_i)$ is controllable for some $j \in \{1, 2, \cdots, N\}$ with $[e_i TD]_j \neq 0$. Then, by Lemma 3, for each left eigenvector $\xi$ of $A_i + \lambda_i H, \xi B_j \neq 0$. From this idea, we can derive the following result as a corollary of Theorem 2, which gives a sufficient condition for controllability.
Corollary 1. Let $T$ be a non-singular matrix triangularizing matrix $C$, such that $T \otimes I$ commutes with $A$. If $J$ contains a Jordan block of order $l \geq 2$ corresponding to the eigenvalue $\lambda_{ij}$ of $C$, then assume that $\xi_{ij}^k H = 0$ for all $i = i_0, i_0 + 1, \ldots, i_0 + l - 1$, $j = 1, 2, \ldots, q_i$, $k = 1, 2, \ldots, \gamma_{ij}$, where $\xi_{ij}^k i = 1, 2, \ldots, N, j = 1, 2, \ldots, q_i, k = 1, 2, \ldots, \gamma_{ij}$ are the left eigenvectors of $A_i + \lambda_i H$ corresponding to the eigenvalues $\mu_{ij}^i, i = 1, 2, \ldots, N, j = 1, 2, \ldots, q_i$. Then, the networked system (3) is controllable if the following conditions are satisfied.

(i) $e_iT D \neq 0$ for all $i = 1, \ldots, N$;
(ii) For a fixed $i$, $(A_i + \lambda_i H, B_i)$ is controllable for some $j \in \{1, 2, \ldots, N\}$ with $[e_iT D]_j \neq 0$;
(iii) If matrices $A_1 + \lambda_1 H, A_2 + \lambda_2 H, \ldots, A_{p+1} + \lambda_{p+1} H(\lambda_i \in \sigma(C), k = 1, \ldots, p$, where $p > 1$) have a common eigenvalue $\sigma$, then $(e_i T \otimes \xi_{ij}^k) B, \ldots, (e_i T \otimes \xi_{ij}^{p+1}) B, \ldots, (e_i T \otimes \xi_{ij}^p) B$ are linearly independent vectors, where $\gamma_{ik} \geq 1$ is the geometric multiplicity of $\sigma$ for $A_{ik} + \lambda_{ik} H$ and $\xi_{ik}^l (l = 1, \ldots, \gamma_{ik})$ are the left eigenvectors of $A_{ik} + \lambda_{ik} H$ corresponding to $\sigma, k = 1, \ldots, p$.

Example 3. Consider a networked system with three nodes, where the dynamics of the system is given as follows:

$$A_1 = A_2 = A_3 = \begin{bmatrix} 1 & 1 & 0 \\ 2 & 1 & 2 \\ 0 & 2 & 1 \end{bmatrix}, \quad B_1 = \begin{bmatrix} 1 \\ 0 \\ 0 \end{bmatrix}, \quad B_2 = \begin{bmatrix} 1 \\ 0 \\ 0 \end{bmatrix}, \quad B_3 = \begin{bmatrix} 1 \\ 0 \\ 0 \end{bmatrix}, \quad H = \begin{bmatrix} 0 & 1 & 0 \\ 1 & 0 & 1 \\ 0 & 1 & 1 \end{bmatrix}$$

(10)

The network topology matrix and the eternal input matrix are given by

$$C = \begin{bmatrix} 0 & 0 & 1 \\ 1 & 0 & 0 \\ 1 & 0 & 0 \end{bmatrix}, \quad D = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 0 \end{bmatrix}$$

(11)

$C$ is diagonalizable with $T = \begin{bmatrix} 0 & 1 & -1 \\ \sqrt{3} & 0 & \sqrt{3} \\ \sqrt{3} & 0 & -\sqrt{3} \end{bmatrix}$, such that $TCT^{-1} = \begin{bmatrix} 0 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & -1 \end{bmatrix} = I$. We have $\lambda_1 = 0, \lambda_2 = 1$ and $\lambda_3 = 1$. Clearly, $J$ does not contain any Jordan blocks and $T \otimes I$ commutes with $A$. Then

(i) as $TD = \begin{bmatrix} 0 & 1 & 0 \\ \sqrt{3} & 0 & 0 \\ -\sqrt{3} & 0 & 0 \end{bmatrix}$, $e_i T D \neq 0$ for all $i = 1, 2, 3$.

(ii) We have $[e_1 T D]_2, [e_2 T D]_1, [e_3 T D]_1 \neq 0$. Here $(A_1, B_2), (A_2 + H, B_1)$ and $(A_1 - H, B_2)$ are controllable.

(iii) Here, $A_1$ and $A_3 - H$ has a common eigenvalue, $\sigma = 1$. The corresponding left eigenvectors are, respectively, $\xi = [-2 \ 0 \ 1]$ and $\nu = [1 \ 0 \ 0]$. Clearly, $(e_i T \otimes \xi) B \neq 0$ and $(e_i T \otimes \nu) B \neq 0$.

Thus, all the conditions of Corollary 1 are satisfied and hence the given system is controllable.

If $B_j = B$ for all $i = 1, 2, \ldots, N$, then the following result by Ajayakumar et al. [26] can be obtained as a consequence of Corollary 1.

Theorem 3 ([26]). Let $T$ be a non-singular matrix triangularizing matrix $C$, such that $T \otimes I$ commutes with $A$. If $J$ contains a Jordan block of order $l \geq 2$ corresponding to the eigenvalue $\lambda_{ij}$ of $C$, then assume that $\xi_{ij}^k H = 0$ for all $i = i_0, i_0 + 1, \ldots, i_0 + l - 1, j = 1, 2, \ldots, q_i, k = 1, 2, \ldots, \gamma_{ij}$, where $\xi_{ij}^k i = 1, 2, \ldots, N, j = 1, 2, \ldots, q_i, k = 1, 2, \ldots, \gamma_{ij}$ are the left eigenvectors of $A_i + \lambda_i H$ corresponding to the eigenvalues $\mu_{ij}^i i = 1, 2, \ldots, N, j = 1, 2, \ldots, q_i$. Then, the networked system (3) is controllable if, and only if,
(i) $\varepsilon_i TD \neq 0$ for all $i = 1, \ldots, N$;
(ii) $(A_i + \lambda_i H, B)$ is controllable, for $i = 1, 2, \ldots, N$;
(iii) If matrices $A_{i1} + \lambda_{i1} H, A_{i2} + \lambda_{i2} H, \ldots, A_{ip} + \lambda_{ip} H (\lambda_k \in \sigma(C), k = 1, \ldots, p$, where $p > 1$) have a common eigenvalue $\sigma$, then $(\varepsilon_i TD) \otimes (\xi_i^{1} B), \ldots, (\varepsilon_i TD) \otimes (\xi_i^{1} B), \ldots, (\varepsilon_i TD) \otimes (\xi_i^{1} B), \ldots, (\varepsilon_i TD) \otimes (\xi_i^{1} B)$ are linearly independent vectors, where $\gamma_k \geq 1$ is the geometric multiplicity of $\sigma$ for $A_{i1} + \lambda_{i1} H$ and $\xi_i^{1} (l = 1, \ldots, \gamma_i)$ are the left eigenvectors of $A_{i1} + \lambda_{i1} H$ corresponding to $\sigma, k = 1, \ldots, p$.

Controllability Results in a Special Network Topology

Now we will discuss the controllability of system (6), when the network topology is given by an upper/lower triangular matrix and the state matrices have certain properties. Here, also, we will characterize the eigenvalues and eigenvectors of the state matrix $F$.

**Theorem 4.** Assume that $C$ is an upper triangular matrix. Let $\sigma(A_i + c_i H_i) = \{\mu_{i1}, \mu_{i2}, \ldots, \mu_{in}\}$ be the set of eigenvalues of $A_i + c_i H_i, i = 1, 2, \ldots, N$. Then, the set of all eigenvalues of $F$ is given by $\sigma(F) = \{\mu_{i1}^{1}, \mu_{i2}^{1}, \ldots, \mu_{i1}^{n}, \mu_{i2}^{n}, \ldots, \mu_{in}^{n}\}$. Let $\xi_{ij}^k, k = 1, 2, \ldots, \gamma_{ij}$ be the left eigenvectors of $A_i + c_i H_i$ associated with the eigenvalue $\mu_{ij}^k$, where $\gamma_{ij}$ is the geometric multiplicity of $\mu_{ij}^k$ for $A_i + c_i H_i$. If $\xi_{ij}^k H_i = 0$, for $i = 1, 2, \ldots, N - 1, j = 1, 2, \ldots, q_i, k = 1, 2, \ldots, \gamma_{ij}$, then $e_i \otimes \xi_{ij}^1, e_i \otimes \xi_{ij}^2, \ldots, e_i \otimes \xi_{ij}^{q_i}$, are the left eigenvectors of $F$ associated with the eigenvalues $\mu_{ij}^k$.

**Proof.** Suppose that $C$ is an upper triangular matrix, say $C = \begin{bmatrix} c_{11} & c_{12} & \cdots & c_{1N} \\ c_{22} & c_{22} & \cdots & c_{2N} \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \cdots & c_{NN} \end{bmatrix}$.

Then

$$F = \begin{bmatrix} A_1 & 0 & \cdots & 0 \\ 0 & A_2 & \cdots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \cdots & A_N \end{bmatrix} + \begin{bmatrix} c_{11} H_1 & c_{12} H_1 & \cdots & c_{1N} H_1 \\ 0 & c_{22} H_2 & \cdots & c_{2N} H_2 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \cdots & c_{NN} H_N \end{bmatrix} = \begin{bmatrix} A_1 + c_{11} H_1 & c_{12} H_1 & \cdots & c_{1N} H_1 \\ 0 & A_2 + c_{22} H_2 & \cdots & c_{2N} H_2 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \cdots & A_N + c_{NN} H_N \end{bmatrix}$$

is a block upper triangular matrix. Therefore, the eigenvalues of $F$ are precisely the eigenvalues of the matrices $A_i + c_i H_i, i = 1, 2, \ldots, N$. That is, if $\sigma(A_i + c_i H_i) = \{\mu_{i1}^{1}, \mu_{i2}^{1}, \ldots, \mu_{in}^{n}\}$ are the eigenvalues of $A_i + c_i H_i, i = 1, 2, \ldots, N$, then

$$\sigma(F) = \bigcup_{i=1}^{N} \sigma(A_i + c_i H_i) = \{\mu_{i1}^{1}, \mu_{i2}^{1}, \ldots, \mu_{i1}^{n}, \mu_{i2}^{n}, \ldots, \mu_{in}^{n}\}$$

are the eigenvalues of $F$. Now, if $\xi_{ij}^k, k = 1, 2, \ldots, \gamma_{ij}$ represents the left eigenvectors of $A_i + c_i H_i$ associated with the eigenvalue $\mu_{ij}^k$, then clearly $e_N \otimes \xi_{ij}^k, e_N \otimes \xi_{ij}^{2}, \ldots, e_N \otimes \xi_{ij}^{q_i}$, are left eigenvectors of $F$ corresponding to the eigenvalue $\mu_{ij}^k$. If $\xi_{ij}^k H_i = 0$, for $k = 1, 2, \ldots, \gamma_{ij}, i = 1, 2, \ldots, N - 1, j = 1, 2, \ldots, q_i$, then $e_i \otimes \xi_{ij}^1, e_i \otimes \xi_{ij}^2, \ldots, e_i \otimes \xi_{ij}^{q_i}$, are left eigenvectors of $F$ associated with the eigenvalue $\mu_{ij}^k$. Now, we will prove that the only linearly independent left eigenvectors of $F$ are of the form $e_i \otimes \xi_i$, where $\xi_i$ is a left eigenvector of $A_i + c_i H_i$ for some $i$. For example, take $\xi_1, \xi_2, \ldots, \xi_N \in \mathbb{R}^n$, such that
Foundations

We have proved that the left eigenvectors of $F$ are linearly independent. Now, suppose that the networked system (3) is controllable and suppose that these situations contradict our hypothesis. Then by Lemma 3, system (3) is controllable. Thus, if $A_i + c_i H_i$, $i = 1, 2, \ldots, N$ does not have any common eigenvalue, the only left eigenvectors of $F$ are $e_i \otimes \xi_i$, $i = 1, 2, \ldots, N$, where $\xi_i$ are the linearly independent left eigenvectors of $A_i + c_i H_i$ corresponding to the eigenvalue $\mu_i^l$. Now, suppose that $A_{ij} + c_{ij} H_j$, $i = 1, 2, \ldots, N$ have a common eigenvalue $\mu$ with left eigenvectors $\xi_{i1}, \xi_{i2}, \ldots, \xi_{in}$, respectively, where $i_0, i_1, \ldots, i_n \in \{1, 2, \ldots, N\}$. Then, $\sum_{i=1}^n e_i \otimes \xi_i$ is a left eigenvector of $F$ corresponding to the eigenvalue $\mu$.

**Theorem 5.** Let $C$ be an upper/lower triangular matrix. Suppose the eigenvectors of $A_i + c_i H_i$ satisfy the conditions given in Theorem 4, then the networked system (3) is controllable if, and only if,

(i) Every node have external control input.
(ii) $(A_i + c_i H_i, B_i)$ is controllable for all $i = 1, 2, \ldots, N$.

**Proof.** Suppose that the networked system (3) is controllable and suppose that $d_i = 0$ for some $i$, say $i_0$, i.e., $d_{i_0} = 0$. Then the control matrix for the networked system (3) is given by

$$G = \begin{bmatrix} d_1 B_1 & 0 & \cdots & 0 & \cdots & 0 \\ 0 & d_2 B_2 & \cdots & 0 & \cdots & 0 \\ \vdots & \vdots & \ddots & \vdots & \ddots & \vdots \\ 0 & 0 & \cdots & d_{i_0} B_{i_0} & \cdots & 0 \\ \vdots & \vdots & \cdots & \vdots & \ddots & \vdots \\ \vdots & \vdots & \cdots & 0 & \cdots & d_N B_N \end{bmatrix} = \begin{bmatrix} d_1 B_1 & 0 & \cdots & 0 & \cdots & 0 \\ 0 & d_2 B_2 & \cdots & 0 & \cdots & 0 \\ \vdots & \vdots & \ddots & \vdots & \ddots & \vdots \\ 0 & 0 & \cdots & d_{i_0} B_{i_0} & \cdots & 0 \\ \vdots & \vdots & \cdots & \vdots & \ddots & \vdots \\ \vdots & \vdots & \cdots & 0 & \cdots & d_N B_N \end{bmatrix}$$

We have proved that $e_{i_0} \otimes \xi_{i_0}^k$, $k = 1, 2, \ldots, \gamma_{i_0 j}$ are left eigenvectors of $F$ corresponding to the eigenvalue $\mu_{i_0 j}^l$, where $j = 1, 2, \ldots, q_{i_0}$. Observe that for any $j = 1, 2, \ldots, q_{i_0}$, $k = 1, 2, \ldots, \gamma_{i_0 j}$, $\left( e_{i_0} \otimes \xi_{i_0}^k \right) G = 0$. Then, by Lemma 3, the given system is not controllable, which is a contradiction. Now, suppose that $(A_i + c_i H_i, B_i)$ is not controllable for some $i$, say $i_1$. Again by Lemma 3, for some eigenvalue $\mu_{i_1}^l$ (where $j_1 \in \{1, 2, \ldots, q_{i_1}\}$) of $A_{i_1} + c_{i_1} H_{i_1}$ there exists a left eigenvector $\xi_{i_1 j_1}$ (where $k_1 \in \{1, 2, \ldots, \gamma_{i_1 j_1}\}$), such that $\xi_{i_1 j_1} B_{i_1} = 0$. Then clearly $\left( e_i \otimes \xi_{i_1 j_1} \right) G = 0$, which is a contradiction. Conversely, suppose that both (i) and (ii) are satisfied. We have the left eigenvectors of $F$ are $e_i \otimes \xi_i^k$, where $i = 1, 2, \ldots, N$, $j = 1, 2, \ldots, q_i$, $k = 1, 2, \ldots, \gamma_{ij}$ or their linear combinations. Now $\left( e_i \otimes \xi_{ij}^k \right) G = 0$ if, and only if, either $d_i = 0, \xi_{ij}^k B_i = 0$ or both for some $i$. Both of these situations contradict our hypothesis. Then by Lemma 3, system (3) is controllable. □
Example 4. Consider a heterogeneous networked system with three nodes, where the state matrices and control matrices are given by

\[
A_1 = \begin{bmatrix} 1 & 2 & 1 \\ 1 & 1 & -1 \\ 0 & 1 & 2 \end{bmatrix}, \quad A_2 = \begin{bmatrix} 1 & 0 & 0 \\ -1 & 1 & 0 \\ 0 & -1 & 1 \end{bmatrix}, \quad A_3 = \begin{bmatrix} 1 & 1 & -1 \\ 0 & 1 & 0 \\ 0 & -1 & 1 \end{bmatrix}, \quad B_1 = \begin{bmatrix} 1 \\ 0 \end{bmatrix}, \quad B_2 = \begin{bmatrix} 1 \\ -1 \end{bmatrix}, \quad B_3 = \begin{bmatrix} 0 \\ 1 \end{bmatrix}
\]

The inner-coupling matrices are given by,

\[
H_1 = \begin{bmatrix} 1 & 1 & -1 \\ 0 & 0 & 0 \\ 1 & 1 & -1 \end{bmatrix}, \quad H_2 = \begin{bmatrix} 0 & 0 & 0 \\ 1 & 2 & 0 \\ -1 & 0 & 1 \end{bmatrix}, \quad H_3 = \begin{bmatrix} 1 & 0 & 2 \\ 0 & 0 & 0 \\ 2 & -1 & 1 \end{bmatrix}
\]

The left eigenvectors of \(A_1\) are \(\xi_{11}^1 = [-1, -1, 1]\), \(\xi_{12}^1 = [-1, 1, 1]\) and the only left eigenvector of \(A_2\) is \(\xi_{21}^1 = [1, 0, 0]\). We have \(\xi_{11}^1 H_1 = \xi_{12}^1 H_2 = \xi_{21}^1 H_2 = 0\).

(i) From Figure 4, it is clear that all the nodes have external control input.

(ii) \((A_1, B_1), (A_2, B_2)\) and \((A_3, H_3, B_3)\) are controllable.

Thus, all the conditions of Theorem 5 are satisfied. Therefore, the given networked system is controllable.

Figure 4. Take \(c_{12} = c_{13} = c_{23} = c_{33} = 1\), otherwise \(c_{ij} = 0\) and \(d_1 = d_2 = d_3 = 1\).

5. Conclusions and Future Scope of Work

This paper provides a necessary and sufficient condition for the controllability of a heterogeneous networked system. Ajayakumar et al. [26] analyzed heterogeneous networked systems having identical control matrices in each node and obtained a necessary and sufficient conditions for controllability. Based on this work, it is possible to identify the nodes that required external control inputs in order to make the uncontrollable system controllable. In the present work, control matrices are considered to be distinct in each node and in addition to identifying the nodes that will receive control inputs, it is also possible to identify the control input matrices that needed to be employed. The existing results tell us less than ours about how subsystem dynamics, network topology, etc., affect the controllability of a networked system, and our results are easy to validate. In addition, controllability results for a more general class of heterogeneous networked systems over a particular network topology are obtained. We plan to look into the controllability of networked systems over more general network topologies in the future. The ability to control networked systems with delays and impulses could be another study area. However, research is performed in this direction for homogeneous networked systems with one-way communication and control delays, and this kind of study still needs to be performed on heterogeneous networked systems.
