Abstract: In this paper, the approximate stationarity of the second-order moment increments of the sub-fractional Brownian motion is given. Based on this, the pricing model for European options under the sub-fractional Brownian regime in discrete time is established. Pricing formulas for European options are given under the delta and mixed hedging strategies, respectively. Furthermore, European call option pricing under delta hedging is shown to be larger than under mixed hedging. The hedging error ratio of mixed hedging is shown to be smaller than that of delta hedging via numerical experiments.

Keywords: discrete-time model; sub-fractional Brownian motion; delta hedging; mixed hedging; hedging error ratio

1. Introduction

The most well-known model of option pricing is the Black–Scholes (BS) model [1]. As the random driving source of the risk asset price in the BS model is Brownian motion, it cannot capture many of the characteristic features of the risk asset price, including long-range dependence, heavy tails, and periods of constant values, etc. In order to overcome these shortcomings, scholars adopt other stochastic processes as the random source of the option pricing model, such as fractional Brownian motion [2–7], mixed fractional Brownian motion [8–12], time-changed Brownian motion [13–16], skew Brownian motion [17–21], etc.

Recently, researchers have proposed a new stochastic process called sub-fractional Brownian motion (sfBm) as the random driving source of the option pricing model. sfBm $B^H_t = \{ B^H_t, t \geq 0 \}$ is a centered Gaussian process with $B^H_0 = 0$ and was proposed by Bojdecki et al. in 2004 [22]. The covariance of sfBm is given by

$$\text{Cov}(B^H_t, B^H_s) = t^{2H} + s^{2H} - \frac{1}{2} [(t + s)^{2H} + |t - s|^{2H}],$$

where $0 < H < 1$ is the Hurst parameter. For $H = \frac{1}{2}$, $B^H_t$ becomes a standard Brownian motion.

From Equation (1), we can find that sfBm has the following properties: (1) self-similarity—for any $x > 0$, $(B^H_{tx})_{t \geq 0}$ has the same distribution as $(x^H B^H_t)_{t \geq 0}$; (2) long-term dependence—for $\frac{1}{2} < H < 1$, $\sum_{n=1}^{\infty} \text{Cov}(B^H_n, B^H_{n+1} - B^H_n) = \infty$. The above two properties are the same as in fractional Brownian motion. However, differing from fractional Brownian motion, sfBm has non-stationarity in the second moment increments. One can refer to [23–27] for more details of the sfBm.

In recent years, many scholars have studied the pricing problems for options under the sfBm regime. Araneda and Bertschinger [28] proposed the sub-fractional Constant Elasticity of Variance (CEV) model. Based on the transition probability density function of the underlying asset price, they derived the explicit formulas for European options. Wang et al. [29] researched the geometric Asian power option pricing model in the sfBm environment. They derived a closed-form pricing formula for geometric Asian power options.
options based on the Itô formula of sfBm. Wang et al. [30] put forward a new Poisson process based on sfBm. Furthermore, they established the sub-fractional Poisson volatility model for option pricing and obtained the closed-form pricing formulas for European options. Bian and Li [31] considered the European option pricing model in an uncertain environment based on sfBm. Their results indicate that in an uncertain environment, a random source of underlying assets with long-term dependence is more suitable for the financial market. Xu and Li [32] gave the pricing formulas for compound options in the sub-fractional Brownian motion model using the risk neutral valuation method.

However, all the above models are continuous-time models. What about the case of discrete time? As the second moment increments of sfBm are not stationary, it is not easy to build a discrete-time model for options in the sfBm regime. Fortunately, we find that the second moment increments of sfBm are approximately stationary. Based on this, we consider the European option pricing under sfBm in discrete time. Moreover, in the discrete-time model of option pricing, delta hedging is the main hedging method. However, Wang [33] proposed a new hedging strategy called mixed hedging. Under this new hedging method, they obtained a discrete-time pricing formula for European options in the Brownian motion regime. Furthermore, their numerical experiments showed that the hedging error ratio of delta hedging was larger than in the mixed one. Kim et al. [34] considered the European option pricing model in the time-changed mixed fractional Brownian regime using the mixed hedging method. Their numerical results were consistent with those of Wang [32], i.e., the hedging error ratio of delta hedging is larger than that of the mixed one in some situations.

Based on the above, in this paper, we will consider the European option pricing model under the sfBm environment in discrete time. In Section 2, we will give the approximate stationarity of second-order moment increments of sfBm. Based on the approximate stationarity, in Section 3, we will establish the discrete-time model for European option pricing under the delta hedging strategy and mixed hedging strategy, respectively. In Section 4, we will give some numerical analysis to further evaluate the model. In Section 5, we conclude this paper.

2. Approximate Stationarity of the Second Moment Increments of sfBm

From the covariance of sfBm, we can obtain the following conclusion.

Lemma 1. The sfBm \( B_t^H \) satisfies the following property:

\[
E[(B_{t+\Delta t}^H - B_t^H)^2] = (\Delta t)^{2H} + o(\Delta t^{2H}).
\] (2)

Proof. From the covariance of sfBm, we know that

\[
E[(B_{t+\Delta t}^H - B_t^H)^2] = E[(B_{t+\Delta t}^H)^2 - 2B_{t+\Delta t}^H B_t^H + (B_t^H)^2]
= E[(B_{t+\Delta t}^H)^2] - 2E[(B_{t+\Delta t}^H B_t^H)] + E[(B_t^H)^2]
= 2(t + \Delta t)^{2H} - \frac{1}{2}(2t + 2\Delta t)^{2H} + 2t^{2H} - \frac{1}{2}(2t)^{2H}
- 2\{(t + \Delta t)^{2H} + t^{2H} - \frac{1}{2}(2t + \Delta t)^{2H} + (\Delta t)^{2H}\}
= \frac{1}{2}[(2t + 2\Delta t)^{2H} + (2t + \Delta t)^{2H} + (\Delta t)^{2H} - \frac{1}{2}(2t)^{2H}
- (\Delta t)^{2H}]
= -(2H - 1)(2t)^{2H-1}(\Delta t)^{2H} - (2t)^{2H} - (\Delta t)^{2H}
= (\Delta t)^{2H} + o(\Delta t^{2H}).
\]
As $-H(2H - 1)(2t)^{2H - 2} (\Delta t)^2$ is $o(\Delta t^{2H})$, we have that
\[
E[(B^H_{t+\Delta t} - B^H_t)^2] \approx (\Delta t)^{2H},
\]
(3)
then
\[
E[(B^H_t - B^H_s)^2] \approx (t-s)^{2H}.
\]

In this sense, the second moment increments of sfBm are approximately stationary.

3. European Option Pricing under the Sub-Fractional Geometric Brownian Motion (sfgBm) Model

In this section, we will derive the pricing formulas for European call options in discrete time under the sfgBm model. We choose the same basic assumptions as Guo et al. [35] except the following.

(1) The dynamics of the underlying asset price $S_t$ and a bond price $Q_t$ are given by
\[
S_t = S_0 e^{\mu t + \sigma B^H_t}, \quad S_0 > 0,
\]
and
\[
Q_t = Q_0 e^{rt},
\]
respectively, where $\mu, \sigma, S_0$ are constants, $B^H_t$ is sfBm, and $H > \frac{1}{2}$ is the Hurst parameter.

(2) The value of the option can be replicated by a portfolio $\Pi$ with $X_1(t)$ units of risk asset and $X_2(t)$ units of risk-less bond.

3.1. Pricing Formula for European Call Option in Discrete Time under Delta Hedging Strategy

In this subsection, we will give the discrete-time formulas for European call options under the delta hedging strategy. By $C_t = C(t, S_t)$, we denote the European call option price; then, we have the following.

**Theorem 1.** When the underlying asset price $S_t$ satisfies Equation (4), under the delta hedging strategy $C_t$, it satisfies the following equation,
\[
\frac{\partial C}{\partial t} + rS_t \frac{\partial C}{\partial S_t} + \frac{1}{2} \sigma^2 \frac{\partial^2 C}{\partial S_t^2} - rC = 0,
\]
with the terminal condition $C(T, S_T) = (S_T - K)_+$, and $K$ is the strike price. The European call option price at time $t$ is given by
\[
C(t, S_t) = S_t N(d_1) - Ke^{-r(T-t)} N(d_2),
\]
where
\[
d_1 = \frac{\ln(S_t/K) + (r + \sigma^2/2)(T-t)}{\sigma \sqrt{T-t}}, \quad d_2 = d_1 - \sigma \sqrt{T-t}, \quad \sigma^2 = \sigma^2 (\Delta t)^{2H-1},
\]
and $N(\cdot)$ is the cumulative normal density function.

**Proof.** From Equation (4), we know that
\[
\Delta S_t = S_{t+\Delta t} - S_t = S_t e^{(\mu \Delta t + \sigma \Delta B^H_t)} - 1,
\]
\[
\begin{align*}
&= S_t(\mu \Delta t + \sigma \Delta B^H_t + \frac{1}{2} (\mu \Delta t + \sigma \Delta B^H_t)^2) \\
&\quad + \frac{1}{6} S_t e^{\theta \mu \Delta t + \sigma \Delta B^H_t} (\mu \Delta t + \sigma \Delta B^H_t)^3.
\end{align*}
\]
By the definition of sfBm and Lemma 1, we have
\[ E(\Delta S_t) = S_t \mu \Delta t + \frac{1}{2} \sigma^2 (\Delta t)^{2H} + o((\Delta t)^{2H}). \]  \hspace{1cm} (6)

By the same token, we can derive
\[ E[(\Delta S_t)^2] = S_t^2 \sigma^2 (\Delta t)^{2H} + o((\Delta t)^{2H}). \]  \hspace{1cm} (7)

It is obvious that
\[ \Delta \Pi_t = X_1(t) \Delta S_t + rX_2(t) \Delta t, \]  \hspace{1cm} (8)

and
\[ \Delta C(t, S_t) = \frac{\partial C}{\partial t} \Delta t + \frac{\partial C}{\partial S_t} \Delta S_t + \frac{1}{2} \frac{\partial^2 C}{\partial S_t^2} \Delta S_t^2 + G_1(\Delta t), \]  \hspace{1cm} (9)

where \( E(G_1(\Delta t)) = o((\Delta t)^{2H}) \).

Moreover, from Assumptions (1)–(2) and the delta hedging method, we know that \( C(t, S_t) = X_1(t) S_t + X_2(t) Q_t \) and \( X_1(t) = \frac{\partial C}{\partial S_t} \). Then, from Equations (6)–(9), we have
\[ \Delta \Pi_t = \frac{\partial C}{\partial S_t} \Delta S_t + r(C(t, S_t) - \frac{\partial C}{\partial S_t} S_t) \Delta t, \]  \hspace{1cm} (10)

and
\[ \Delta \Pi_t - \Delta C = (rC - rS_t \frac{\partial C}{\partial S_t} - \frac{\partial C}{\partial t} \Delta t - \frac{1}{2} \frac{\partial^2 C}{\partial S_t^2} \Delta S_t^2 - G_1(\Delta t)). \]  \hspace{1cm} (11)

Subject to \( E(\Delta \Pi_t - \Delta C) = 0 \), we have
\[ \frac{\partial C}{\partial t} + rS_t \frac{\partial C}{\partial S_t} + \frac{1}{2} \sigma^2 (\Delta t)^{2H-1} \frac{\partial^2 C}{\partial S_t^2} - rC = 0. \]  \hspace{1cm} (12)

Denote \( \tilde{\sigma}^2 = \sigma^2 (\Delta t)^{2H-1} \), and we obtain
\[ \frac{\partial C}{\partial t} + rS_t \frac{\partial C}{\partial S_t} + \frac{1}{2} \tilde{\sigma}^2 \frac{\partial^2 C}{\partial S_t^2} - rC = 0. \]  \hspace{1cm} (13)

Furthermore, from the Black–Scholes equation \([1]\), we have
\[ C(t, S_t) = S_t N(d_1) - Ke^{-r(T-t)} N(d_2), \]  \hspace{1cm} (14)

where
\[ d_1 = \frac{\ln(S_t/K) + (r + \tilde{\sigma}^2 / 2)(T-t)}{\tilde{\sigma} \sqrt{T-t}}, \quad d_2 = d_1 - \tilde{\sigma} \sqrt{T-t}. \]  \hspace{1cm} (15)

The proof is completed. \( \Box \)

3.2. Pricing Formula for European Call Option in Discrete Time under Mixed Hedging Strategy

In this subsection, we will obtain the pricing formulas for European call options in discrete time under the sfBm model by using the mixed hedging strategy.

**Theorem 2.** When the price of underlying asset \( S_t \) satisfies Equation (4), the mixed hedging strategy under the sfBm model is given by
\[ X_1(t) = \frac{\partial C}{\partial S_t} + \frac{\mu \Delta t}{1 + \mu \Delta t} \frac{\partial^2 C}{\partial S_t^2} S_t. \]  \hspace{1cm} (16)

**Proof.** From [33], a mixed hedging strategy is the solution of the following problem:
\[ \min_{X_1(t)} \{ \text{Var}_{\Delta t}[\Delta \Pi_t] \}, \]  \hspace{1cm} (17)
subject to

\[ E(\Delta C - \Delta \Pi_t) = 0, \]  

(16)

and

\[ C(t, S_t) = \Pi_t = X_1(t)S_t + rX_2(t)Q_t. \]  

(17)

Denote

\[ A_1(t) = \frac{\partial C}{\partial t} - rX_2(t)Q_t, \]  

(18)

\[ A_2(t) = \frac{\partial C}{\partial S} - X_1(t), \]  

(19)

and

\[ A_3(t) = \frac{1}{2} \frac{\partial^2 C}{\partial S^2}. \]  

(20)

Then, we have

\[ \Delta C - \Delta \Pi_t = (A_1(t) + \mu A_2(t)S_t)\Delta t + [(1 + \mu \Delta t)\sigma S_t A_2(t) + 2\mu \sigma S_t^2 A_3(t) \Delta t] \Delta B_t^H \]

\[ + \left[ \frac{\sigma^2}{\Delta} S_t A_2(t) + \sigma^2 S_t^2 A_3(t) \right] (\Delta B_t^H)^2 + G_2(\Delta t), \]

where \( G_2(\Delta t) = o((\Delta t)^{2H}) \); subject to Equation (16), we can obtain

\[ A_1(t) + (\mu + \frac{\sigma^2}{2}(\Delta t)^{2H-1}) S_t A_2(t) + \sigma^2 S_t^2 A_3(t) (\Delta t)^{2H-1} = 0. \]  

(21)

Let

\[ B_1 = A_1(t) + \mu A_2(t) S_t, \]  

(22)

\[ B_2 = (1 + \mu \Delta t)\sigma S_t A_2(t) + 2\mu \sigma S_t^2 A_3(t) \Delta t, \]  

(23)

\[ B_3 = \frac{\sigma^2}{\Delta} S_t A_2(t) + \sigma^2 S_t^2 A_3(t), \]  

(24)

then, from Lemma 1 we have

\[ E(\Delta C - \Delta \Pi_t)^2 = B_1^2(\Delta t)^2 + B_2^2(\Delta t)^{4H} + B_3^2(\Delta t)^{4H} + 2B_1B_3(\Delta t)^{2H+1}, \]  

(25)

and

\[ E^2(\Delta C - \Delta \Pi_t) = B_1^2(\Delta t)^2 + B_2^2(\Delta t)^{4H} + 2B_1B_3(\Delta t)^{2H+1}. \]  

(26)

Furthermore,

\[ Var(\Delta C - \Delta \Pi_t) = E(\Delta C - \Delta \Pi_t)^2 - E^2(\Delta C - \Delta \Pi_t) \]

\[ = B_2^2(\Delta t)^{2H} = [(1 + \mu \Delta t)\sigma S_t A_2(t) + 2\mu \sigma S_t^2 A_3(t) \Delta t]^2 (\Delta t)^{2H}. \]

Selecting \( X_1(t) \) satisfies the following equation:

\[ \frac{\partial [Var(\Delta C - \Delta \Pi_t)]}{\partial X_1(t)} = 0, \]  

(27)

and by calculation, we have

\[ X_1(t) = \frac{\partial C}{\partial S_t} + \frac{\mu \Delta t}{1 + \mu \Delta t} \frac{\partial^2 C}{\partial S_t^2} S_t. \]  

(28)
Remark 1. The expression of the mixed hedging strategy under the sfBm model is the same as that under the Brownian motion model [33]. This is consistent with the result in [34].

Based on the expression of the mixed hedging strategy, the pricing formula for European call options in discrete time under the sfBm model is given by the following.

**Theorem 3.** When we use the mixed hedging strategy, the European call option price $C(t, S_t)$ satisfies the following equation,

$$
\frac{\partial C}{\partial t} + r_S \frac{\partial C}{\partial S_t} + \frac{(r - \mu)\mu \Delta t + \frac{1}{2} \sigma^2 (\Delta t)^{2H-1}}{1 + \mu \Delta t} \frac{\partial^2 C}{\partial S_t^2} - rC = 0,
$$

and the pricing formula is given by

$$
C(t, S_t) = S_t N(d_3) - Ke^{-r(T-t)} N(d_4), \quad (29)
$$

where

$$
d_3 = \ln(S_t/K) + (r + \hat{\sigma}^2/2)(T-t) / \hat{\sigma} \sqrt{T-t},
$$

$$
d_4 = d_3 - \hat{\sigma} \sqrt{T-t}, \quad (30)
$$

and

$$
\hat{\sigma}^2 = \frac{2(r - \mu)\mu \Delta t + \sigma^2 (\Delta t)^{2H-1}}{1 + \mu \Delta t}. \quad (31)
$$

**Proof.** Substituting Equation (28) into Equations (17)–(21), we can obtain

$$
\frac{\partial C}{\partial t} + r_S \frac{\partial C}{\partial S_t} + \frac{(r - \mu)\mu \Delta t + \frac{1}{2} \sigma^2 (\Delta t)^{2H-1}}{1 + \mu \Delta t} \frac{\partial^2 C}{\partial S_t^2} - rC = 0. \quad (32)
$$

Then, $C(t, S_t)$ satisfies the following final value problem of the partial differential equation:

$$
\left\{ \begin{array}{l}
\frac{\partial C}{\partial t} + r_S \frac{\partial C}{\partial S_t} + \frac{(r - \mu)\mu \Delta t + \frac{1}{2} \sigma^2 (\Delta t)^{2H-1}}{1 + \mu \Delta t} \frac{\partial^2 C}{\partial S_t^2} - rC = 0, \\
c(T, S_T) = (S_T - K)^+. 
\end{array} \right. 
$$

It is easy to see that Equation (32) is a Black–Scholes-type equation. Therefore, from [1], the European call option price can be given by Equations (29)–(31). □

Table 1 shows that the European call option price under delta hedging is larger than under mixed hedging. As the exercise price $K$ increases, the differences in the European call option price between delta hedging and mixed hedging are decreased.

From Figure 1, we can see that the parameter $H$ has an important influence on the European call option price. Moreover, as the parameter $H$ increases, the difference in the European call option price between delta hedging and mixed hedging gradually becomes larger.

**Table 1.** European call option price under delta hedging and mixed hedging across strike price $K$.

4. Numerical Analysis

4.1. Price of European Call Option in Discrete Time under sfBm Model

In this subsection, we will compare the European call option price between delta hedging and mixed hedging. We set $S_0 = 49$, $r = 0.05$, $T = 1$, $\mu = 0.11$, $\sigma = 0.2$, $\Delta t = 0.02$, $H = 0.8$.

4.2. Comparison of Delta Hedging Method and Mixed Hedging Method in sfBm Model

In this subsection, we will compare the delta hedging and the mixed hedging strategies in the sfBm model across the hedging error ratio.

In order to compare the hedging error ratios of the two hedging methods, we use the same example as in [33] (i.e., example 3.1 of [33]). The values of the parameters are $S_0 = 49$, $K = 50$, $\mu = 0.11$, $\sigma = 0.2$, $H = 0.8$.

From Table 2, we can see that the European call option price under delta hedging at week 0 is $71,778.710$. The discount of the total cost of writing the option and hedging to week 0 is equal to $106,355.902$. The hedging error of delta hedging is $(106,355.902 - 71,778.710)/71,778.710$, which is close to 0.48172932.

From Table 3, we can see that the European call option price under mixed hedging is $69,141.684$. The discount of the total cost of writing the option and hedging to week 0 is equal to $97,938.092$. The hedging error of mixed hedging is $(97,938.092 - 71,778.710)/71,778.710$, which is close to 0.48172932.

From Tables 2 and 3, we can see that the hedging error ratio of mixed hedging is less than that of delta hedging.

Table 4 and Figure 2 show the effects of Hurst parameter $H$ on the hedging cost and hedging error ratio when $H$ only varies from 0.65 to 0.9 ($S_0 = 49$, $K = 50$, $\mu = 0.11$, $\sigma = 0.2$).

From Table 4 and Figure 2, we can see that as Hurst parameter $H$ increases, the hedging error ratios of the two hedging methods are both decreased, but the hedging error ratio of mixed hedging decreases faster.

Figure 2. Hedging error ratio across Hurst parameter $H$.

5. Conclusions

This paper deals with the European call option pricing in discrete time under the sfBm model. The numerical results show that the European call option price of delta hedging is larger than the price of mixed hedging. The hedging error ratio of the mixed hedging strategy is less than that of the delta hedging strategy in some situations. Moreover, the Hurst parameter $H$ plays an important role in the European call option price and hedging error ratio. Based on the results of this study, we can study option pricing under sfBm in discrete time; the future research directions mainly include the following.

(i) The real financial market is not smooth. The trading of the risk asset (like stock) always incurs transaction costs and dividends. Therefore, the study of the option pricing model with transaction costs or dividends in the sfBm regime is of great significance.

(ii) The changes in the risk asset price often accompany jumps. Both Brownian motion and sfBm cannot describe this situation. Thus, one can generalize the sfBm model to the jump-diffusion model in discrete time.

Author Contributions: writing—original draft preparation, Z.G. and Y.L.; methodology, Z.G.; writing—review and editing, Z.G. and L.D. All authors have read and agree to the published version of the manuscript.
