Abstract: Two *Castanea* plant species, *C. henryi* and *C. mollissima*, are cultivated in China to produce chestnut crops. Leaf spot diseases commonly occur in *Castanea* plantations, however, little is known about the fungal species associated with chestnut leaf spots. In this study, leaf samples of *C. henryi* and *C. mollissima* were collected from Beijing, Guizhou, Hunan, Sichuan and Yunnan Provinces, and leaf-inhabiting fungi were identified based on morphology and phylogeny. As a result, twenty-six fungal species were confirmed, including one new family, one new genus, and five new species. The new taxa are Pyrisporaceae fam. nov., *Pyrispora* gen. nov., *Aureobasidium castaneae* sp. nov., *Discosia castaneae* sp. nov., *Monochaetia castaneae* sp. nov., *Neopestalotiopsis sichuanensis* sp. nov. and *Pyrispora castaneae* sp. nov.

Keywords: *Castanea henryi*; *C. mollissima*; Diaporthales; phylogeny; Sporocadaceae; taxonomy

1. Introduction

Castanea, a plant genus well-known for edible chestnuts and hard timber, is distributed worldwide. The most four famous species are American chestnut (*C. dentata*), Chinese chestnut (*C. mollissima*), European chestnut (*C. sativa*) and Japanese chestnut (*C. crenata*). *C. mollissima* is widely cultivated as the crop in most provinces of China. In recent years, another *Castanea* species, *C. henryi*, was planted in Hunan Province of China to replace *C. mollissima* for its higher economic benefits.

In the long cultivation history of chestnut trees, fungal diseases have caused serious economic and ecological problems. Chestnut blight caused by *Cryphonectria parasitica* is the most notorious one, which devastated *Castanea dentata* forests in North America and weakened the other chestnut species in plantations [1–3]. Several emerging pathogens were recently reported in *Castanea sativa* from Australia and Europe, *viz.* *Gnomoniopsis smithogilvyi* (syn. *G. castaneae*) [4,5], *Phytophthora cinnamomi* [6], *Sirococcus castanea* [7].

In China, previous studies have revealed a high fungal diversity associated with chestnut branch cankers. For example, three *Coryneum* species [8], two *Cryphonectria* species [2], six *Cytospora* species and seven *Dendrostoma* species were described from the cankered branches [9,10]. In addition, some cryptic species were discovered, such as *Aurantiosacculus castaneae* [2], *Endothia chinensis* [2], *Melanops castaneicola* and *Neopseudomelanconis castaneae* [11,12]. Due to the high fungal diversity on chestnut branches, we collected leaf samples from two chestnut species, *Castanea henryi* and *C. mollissima* in China. In the present study, fungal taxa associated with the symptomatic leaves were identified based on morphological and molecular approaches, which is a fundamental task for the subsequent research on chestnut leaf diseases.

2. Materials and Methods

2.1. Field Sampling and Isolation

From 2017 to 2020, we investigated *Castanea* plantations of *C. henryi* and *C. mollissima* in the Beijing, Guizhou, Hunan, Sichuan and Yunnan Provinces of China. The disease symptoms were recorded (Figure 1), and 176 fresh leaf samples were collected and packed in sealed plastic bags. These leaf samples were transported to the laboratory for fungal isolation within ten days.

Figure 1. Field Sampling. (A) A *Castanea* plantation; (B) Symptoms of twig canker; (C–E,G–I) Symptoms of leaf diseases; (F) Chestnuts.

Fresh isolates were acquired by removing spore masses in fruiting bodies or surface-sterilized leaf tissues onto the surfaces of potato dextrose agar (PDA; 200 g potatoes, 20 g dextrose, 20 g agar per L) using axenic syringe needles. Then plates were incubated in the dark at 25 °C until germination. Hyphal tips were cut and transported to new PDA plates, and incubated in the dark at 25 °C.

2.2. Morphological Identification and Characterization

Fungal species on Chinese chestnut leaves were initially observed based on ascocarps and conidiomata formed on the leaf surface or PDA, under a dissecting stereomicroscope (AZ100, Nikon, Tokyo, Japan), then asci, ascospores, conidiogenous cells and conidia were photographed using a Leica compound microscope (DM 2500, Leica, Wetzlar, Germany). Cultural characteristics of isolates incubated on PDA in the dark at 25 °C were recorded.

2.3. DNA Extraction, Sequencing and Phylogenetic Analysis

Genomic DNA was extracted from mycelium grown on PDA using a CTAB (cetyltrimethylammonium bromide) method [13]. Then PCR (polymerase chain reaction) was conducted for each genus using selected genes and primers (Table 1). The PCR conditions were set as follows: an initial denaturation step of 5 min at 94 °C followed by 35 cycles of 30 s at 94 °C, 50 s at 52 °C (ITS, LSU) or 54 °C (*act*, *cal*, *chs-1*, *gapdh*, *his3*, *rpb2*, *tub2*, *tef1*) and 1 min at 72 °C, and a final elongation step of 7 min at 72 °C. The PCR amplification products were sequenced using an ABI PRISM® 3730XL DNA Analyzer with BigDye® Terminator Kit v.3.1 (Invitrogen) at the Shanghai Invitrogen Biological Technology Company Limited (Beijing, China).

The sequences obtained in this study (Table 2) were supplemented with the additional sequences retrieved from GenBank. The sequences were aligned and checked manually using MEGA6. Ambiguous regions were excluded from the analyses and gaps were treated as missing data. Phylogenetic analyses were carried out with maximum likelihood analysis (ML), which was performed at the CIPRES web portal [21]. Bayesian inference analysis (BI) was performed in MrBayes v. 3.2.0 [22]. Phylogenetic trees were viewed in FigTree v1.4. The names of the isolates from present study are marked in blue in the trees. Maximum likelihood bootstrap support values $\geq 50\%$ (BT) and Bayesian posterior probabilities ≥ 0.90 (PP) are given at the nodes respectively.

3. Results

A total of 26 species were identified, which belonging to two classes, six orders, 13 families and 18 genera in Ascomycota (Table 3). The seven new taxa are Pyrisporaceae fam. nov., *Pyrispora* gen. nov., *Aureobasidium castaneae* sp. nov., *Discosia castaneae* sp. nov., *Monochaetia castaneae* sp. nov., *Neopestalotiopsis sichuanensis* sp. nov. and *Pyrispora castaneae* sp. nov.

Table 3. Fungal species from *Castanea* leaves.

Phylum	Class	Order	Family	Species	Phogeny	Morphology
Ascomycota	Dothideomycetes	Botryosphaerales	Aplosporellaceae	<i>Aplosporella prunicola</i>	Figure A1	NA
			Botryosphaeriaceae	<i>Botryosphaeria dothidea</i>	Figure A2	Figure 2
			Phyllostictaceae	<i>Phyllosticta capitalensis</i>	Figure A3	Figures 3 and 4
		Dothideales	Saccotheciaceae	<i>Aureobasidium castaneae</i>	Figure 5	Figure 6
		Pleosporales	Didymellaceae	<i>Didymella coffeae-arabicae</i>	Figure A4	Figure 7
	Sordariomycetes	Amphisphaerales	Apiosporaceae	<i>Arthrinium arundinis</i>	Figure A5	NA
				<i>Bartalinia pini</i>	Figure A6	Figure 8
				<i>Discosia castaneae</i>	Figure 9	Figure 10
				<i>Monochaetia castaneae</i>	Figure 11	Figure 12
			Sporocadaceae	<i>Neopestalotiopsis asiatica</i>	Figure 13	Figure 14
	Glomerellales	Diaporthales		<i>Neopestalotiopsis brasiliensis</i>	Figure 13	Figure 15
				<i>Neopestalotiopsis sichuanensis</i>	Figure 13	Figure 16
				<i>Neopestalotiopsis sp.1</i>	Figure 13	Figure 17
				<i>Neopestalotiopsis sp.2</i>	Figure 13	Figure 18
				<i>Pestalotiopsis kenyana</i>	Figure A7	Figure 19

				<i>Colletotrichum nymphaeae</i>	Figure A15	NA

3.1. *Aplosporella* Speg.

Aplosporella prunicola Damm & Crous, Fungal Divers. 27(1): 39 (2007)

Endophytic or pathogenic on *Castanea mollissima* leaves. Sexual morph: Undetermined. Asexual morph: Undetermined.

Culture characteristics—Colonies on PDA reaching up to 60 mm in 5 days, flat with undulate edge, olivaceous to grey-olivaceous, aerial mycelium appressed, floccose, white to smoke-grey.

Material examined—CHINA, Sichuan Province, Yaan City, Shimian County, 29°13'31" N, 102°21'27" E, alt. 978 m, on leaf spots of *Castanea mollissima*, 10 September 2020, N. Jiang (living culture, CFCC 54334 = SM18B); *ibid.* (living culture, SM18B-1).

Notes—*Aplosporella prunicola* was initially recorded from *Prunus persica* var. *nucipersica* in South Africa [23]. Two new isolates from diseased chestnut leaves in present study are phylogenetically close to *Aplosporella prunicola* (Figure A1) and share similar culture characteristics on PDA. This is the first report of this fungus on the host *Castanea mollissima*, and in the Country China.

3.2. *Botryosphaeria* Ces. & De Not.

Botryosphaeria dothidea Ces. & De Not., Comm. Soc. crittog. Ital. 1(fasc. 4): 212 (1863) (Figure 2)

Pathogenic on *Castanea henryi* and *C. mollissima* leaves. Sexual morph: Undetermined. Asexual morph: Conidiomata 100–250 µm diam., pycnidial, aggregated, globose, black. Conidiophores absent. Conidiogenous cells 3–11 × 1.5–3 µm, holoblastic, discrete, hyaline, cylindrical to lageniform, phialidic with periclinal thickening. Conidia (18.3–)20–24.7(–26.4) × (6.3–)7.2–8.4(–8.7) µm ($\bar{x} = 22.3 \times 7.8 \mu\text{m}$, $n = 50$), L/W = (2.3–)2.4–3.4(–3.9) ($\bar{x} = 2.9$, $n = 50$), hyaline, thin-walled, smooth with granular contents, unicellular, aseptate, ellipsoid to fusoid, base subtruncate to bluntly rounded.

Culture characteristics—Colonies on PDA reaching up to 60 mm in 4 days, initially white with fluffy, aerial mycelium, becoming black on the surface after 5 days; reverse side of the colonies dark-brown.

Material examined—CHINA, Hunan Province, Changsha City, Changsha County, Jinjing Town, 28°58'52" N, 113°34'38" E, alt. 63 m, on leaf spots of *Castanea henryi*, 10 November 2020, C.M. Tian & N. Jiang (BJFC-S1823; living culture, JJ 2B); *ibid.* (living cultures, CFCC 54576 = JJ12, JJ14, JJ27-1); Hunan Province, Shaoshan City, Yintian Town, 27°52'04" N, 112°35'03" E, alt. 73 m, on leaf spots of *Castanea mollissima*, 9 November 2020, C.M. Tian & N. Jiang (living culture, CFCC 54585 = SS9-1); Beijing City, Haidian District, 40°00'30" N, 116°20'26" E, alt. 23 m, on leaf spots of *Castanea mollissima*, 28 August 2020, N. Jiang (BJFC-S1797).

Notes—The genus *Botryosphaeria* is presently not well separated phylogenetically [24–26]. In the phylogenetic inference of ITS, *tef1* and *tub2* sequence data (Figure A2), four new isolates from this study are close to *B. auasmontanum*, *B. dothidea*, *B. minutispermatica*, *B. qinlingensis*, *B. sinensis* and *B. wangensis*. Phylogenetic analyses based on more collections of this genus are necessary to clarify species concept in the future. In present study, we provide the morphology and phylogeny of samples from *Castanea* leaves, and identified these isolates as *Botryosphaeria dothidea* s. l.

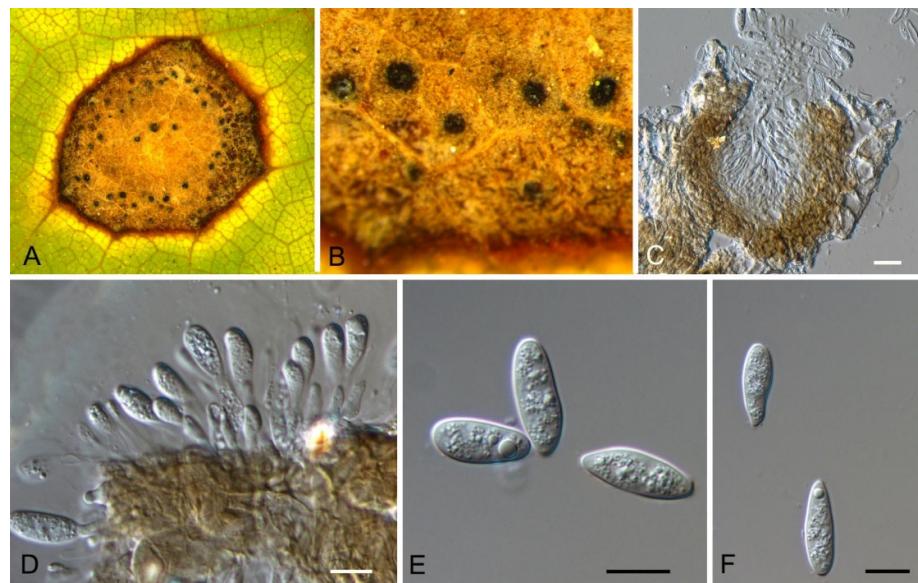

Figure 2. *Botryosphaeria dothidea* (BJFC-S1797). (A,B) Conidiomata on the diseased leaves of *Castanea mollissima*; (C) Section through the pycnidium; (D) Conidiogenous cells giving rise to conidia; (E,F) Conidia. Scale bars: C = 15 µm; C–F = 10 µm.

3.3. *Phyllosticta* Pers.

Phyllosticta capitalensis Henn., Hedwigia 48: 13 (1908) (Figures 3 and 4)

Pathogenic on *Castanea henryi* and *C. mollissima* leaves. Sexual morph: Ascomata 80–200 µm diam., globose to pyriform, black. Ascii 62–85 × 8–12.5 µm, bitunicate, clavate to broadly fusoid-ellipsoid. Ascospores (13.2–)14.6–16.2(–17.4) × (3.7–)4.1–5.2(–6.8) µm ($\bar{x} = 15.1 \times 4.5$ µm, $n = 30$), L/W = (2.8–)2.9–4(–4.1) ($\bar{x} = 3.5$, $n = 30$), bi-seriate, hyaline, smooth, 1-septate or aseptate, guttulate, straight and slightly curved, widest in the middle, limoniform with obtuse ends, with distinct hyaline gelatinous caps at both ends, 3–5 × 1.5–3 µm. Asexual morph: Conidiomata 100–250 µm diam., pycnidial, scattered or aggregated, globose to subglobose, black. Pycnidial wall of several layers, composed of cells of *textura angularis*, thick, inner wall of hyaline *textura angularis* cells. Conidiophores reduced to conidiogenous cells. Conidiogenous cells 3–12 × 2.5–5.5 µm, terminal, subcylindrical to ampulliform to doliiform, hyaline, smooth, proliferating several times percurrently near apex. Conidia (9–)10–11.8(–12.4) × (6.8–)7.4–8.3(–8.6) µm ($\bar{x} = 10.9 \times 7.8$ µm, $n = 50$), L/W = (1.1–)1.3–1.5(–1.6) ($\bar{x} = 1.4$, $n = 50$), solitary, hyaline, aseptate, thin and smooth walled, with a single large central guttulate, obovoid, tapering towards a narrow truncate base, enclosed in a persistent mucoid sheath, 2–7 µm thick.

Culture characteristics—Colonies on PDA reaching up to 40 mm in 10 days, flat, initially white-grey mycelium, gradually becoming greenish to dark brown, with white hyphae at the margin; reverse black.

Material examined—CHINA, Hunan Province, Changsha City, Changsha County, Jinjing Town, 28°58'52" N, 113°34'38" E, alt. 63 m, on leaf spots of *Castanea henryi*, 10 November 2020, C.M. Tian & N. Jiang (BJFC-S1821; living culture, JJ4); *ibid.* (BJFC-S1822; living culture, CFCC 54576 = JJ11); *ibid.* (living cultures, CFCC 54577 = JJ16, JJ20); Hunan Province, Shaoshan City, Yintian Town, 27°52'04" N, 112°35'03" E, alt. 73 m, on leaf spots of *Castanea mollissima*, 9 November 2020, C.M. Tian & N. Jiang (BJFC-S1820; living culture, SS5); *ibid.* (living cultures, SS10, SS13, SS15, SS16-1, SS16-2); Hunan Province, Xiangtan City, 27°48'51" N, 112°71'42" E, alt. 85 m, on leaf spots of *Castanea mollissima*, 9 November 2020, N. Jiang (BJFC-S1819; living culture, XT2); *ibid.* (living cultures, XT10, XT11, XT16-1, XT16-2, XT17); Yunnan Province, Zhaotong City, Zhenxiong County, 27°43'28" N, 105°10'35" E, alt. 1280 m, on leaf spots of *Castanea mollissima*, 5 September 2020, N. Jiang (living cultures, ZX6, ZX11-1); Guizhou Province, Zunyi City, Goujiang Town, 27°24'49" N, 106°52'49" E, alt. 1064 m, on leaf spots of *Castanea mollissima*, 7 September 2020, N. Jiang (living culture, ZY6-1).

Notes—The genus *Phyllosticta* is a worldwide genus of pathogens, endophytes and saprobes, which was separated into six species complexes [27]. In the present study, we observed the sexual and asexual morphs on *Castanea* leaves, and identified them as *Phyllosticta capitalensis* s. s. based on the phylogenetic inference of ITS, LSU, *act*, *gapdh* and *tef1* sequence data (Figure A3).

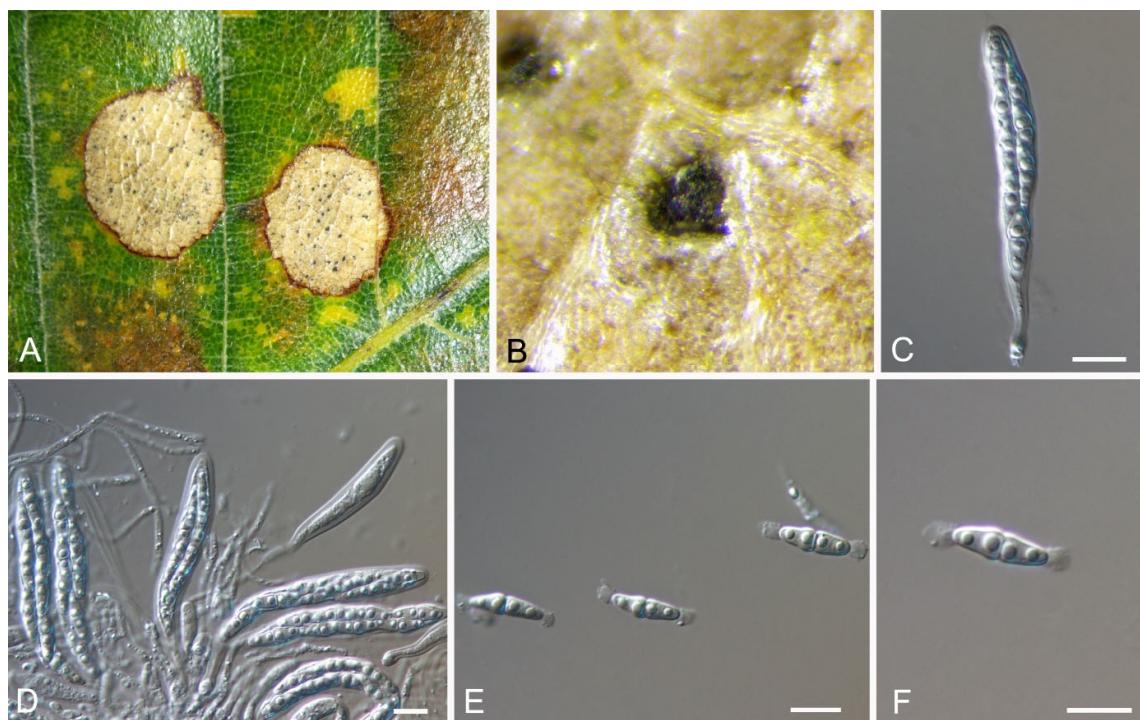

Figure 3. *Phyllosticta capitalensis* (BJFC-S1821). (A,B) Ascostromata on the diseased leaves of *Castanea mollissima*; (C,D) Asci; (E,F) Ascospores. Scale bars: C–F = 10 μ m.

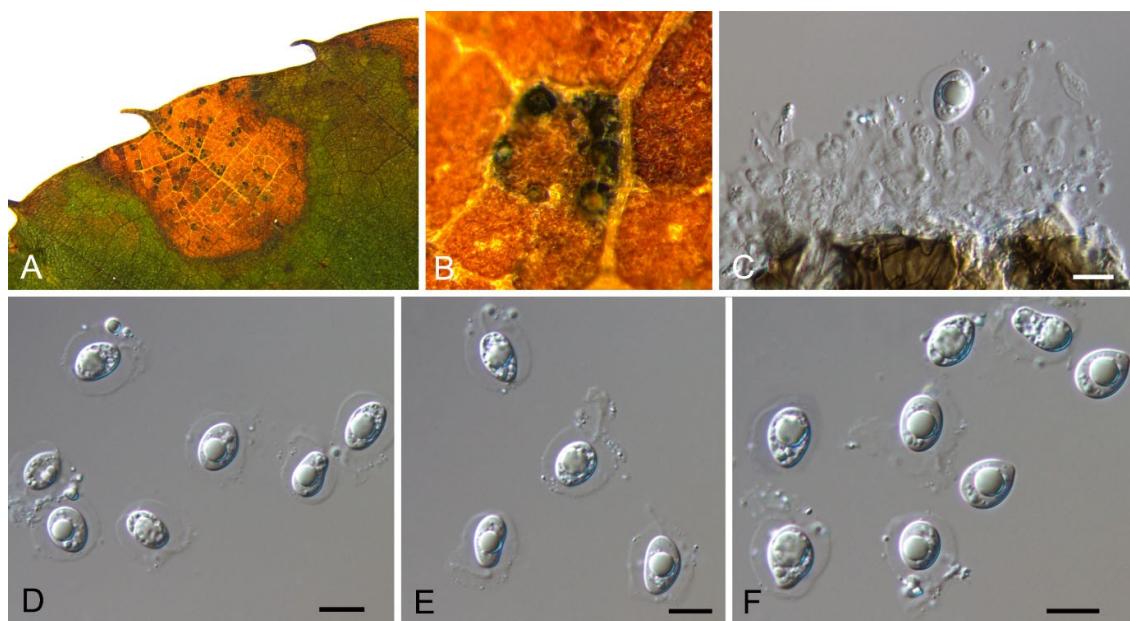

Figure 4. *Phyllosticta capitalensis* (BJFC-S1820). (A,B) Conidiomata on the diseased leaves of *Castanea mollissima*; (C) Conidigenous cells giving rise to conidia; (D–F) Conidia. Scale bars: C–F = 10 μ m.

3.4. *Aureobasidium* Viala & G. Boyer

Aureobasidium castaneae C.M. Tian & N. Jiang, sp. nov. (Figure 6)

Mycobank: MB 838314

Etymology—named after the host genus, *Castanea*.

Holotype—BJFC-C007

Endophytic or pathogenic on *Castanea henryi* leaves. Sexual morph: Undetermined. Asexual morph was observed on PDA: Mycelium immersed, no aerial mycelium. Hyphae 3–7 µm wide, smooth, thin-walled, septate, hyaline or brown. Conidiogenous cells undifferentiated, hyaline or brown, intercalary or rarely terminal. Conidia (5.9–)7.1–10.6(–11.8) × (2.7–)2.7–4.7(–6.2) µm ($\bar{x} = 8.9 \times 3.7$ µm, $n = 50$), L/W = (1.8–)2.1–2.8(–3.1) ($\bar{x} = 2.4$, $n = 50$), hyaline or brown based on the color of conidiogenous cells, variable in size, ellipsoidal, straight, rarely slightly curved, with rounded to subtruncate base and a flat basal hilum, thin-walled, with two or more guttules.

Culture characteristics—Colonies on PDA reaching up to 40 mm in 7 days, spreading, smooth, flat, rapidly turning to olivaceous black, with dark green, irregular margins, covered with slimy masses of conidia.

Material examined—CHINA, Hunan Province, Changsha City, Changsha County, Jinjing Town, 28°58'52" N, 113°34'38" E, alt. 63 m, on leaf spots of *Castanea henryi*, 10 November 2020, C.M. Tian & N. Jiang (BJFC-C007, holotype; ex-type living culture, CFCC 54591 = JJ 7-3).

Notes—*Aureobasidium* is a well-known genus comprising saprophytes, endophytes and pathogens on various substrates [28–32]. *A. castaneae* from *Castanea henryi* in this study is closely related to *A. thailandense* from unknown plants based on phylogenetic inference of ITS and LSU sequence data (Figure 5). However, *A. castaneae* can be easily distinguished from *A. thailandense* by conidial size (7.1–10.6 × 2.7–4.7 µm in *A. castaneae* vs. 3–10 × 5–12 µm in *A. thailandense*) [31].

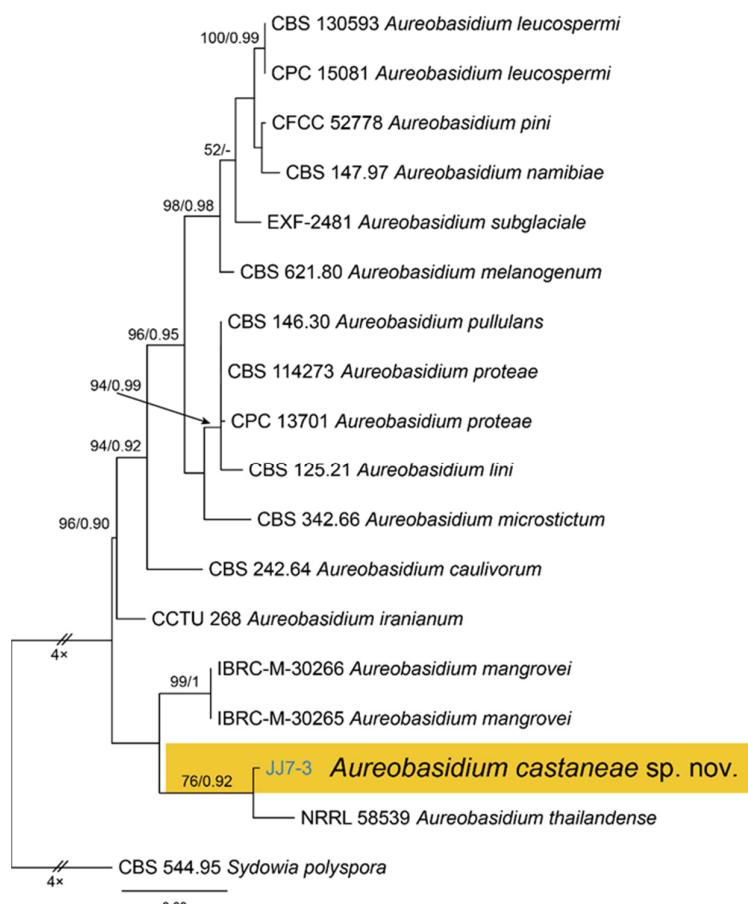

Figure 5. Phylogram generated from RAxML analysis based on combined ITS and LSU sequence data of *Aureobasidium* isolates. The tree was rooted to *Sydowia polyspora* (CBS 544.95). The scale bar indicates 0.03 nucleotide changes per site. Isolate from this study is marked in blue, and the identified species is marked in yellow.

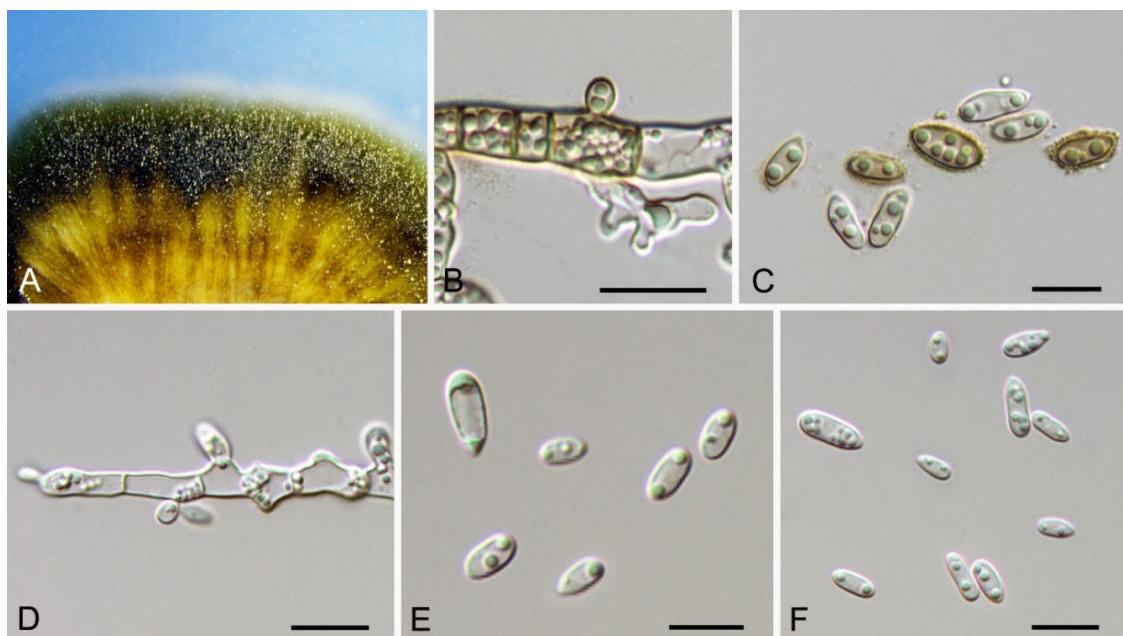

Figure 6. *Aureobasidium castaneae* (BJFC-C007, holotype). (A) Colony on PDA; (B,D) Conidiogenous cells and conidia; (C,E,F) Conidia. Scale bars: B–F = 10 μ m.

3.5. *Didymella* Sacc.

Didymella coffeae-arabicae Qian Chen & L. Cai, Stud. Mycol. 82: 175 (2015) (Figure 7)

Pathogenic on *Castanea mollissima* leaves. Sexual morph: Undetermined. Asexual morph: Conidiomata 120–200 μ m diam., 100–180 μ m high, pycnidial, conspicuous, stromatic, scattered or aggregated, globose to subglobose, dark brown, with septate and dark hyphal outgrowths. Ostioles single, centric. Pycnidial wall pseudoparenchymatous, composed of isodiametric cells, 3–5 layers, 8–20 μ m thick. Conidiogenous cells phialidic, hyaline, simple, smooth, flask-shaped to globose. Conidia (3.1–)3.7–4.8(–4.9) \times (1.8–)2.1–2.7(–2.8) μ m (\bar{x} = 4.3 \times 2.4 μ m, n = 50), L/W = (1.3–)1.5–2.2(–2.6) (\bar{x} = 1.8, n = 50), ellipsoidal to ovoid, thin-walled, smooth, hyaline, always aseptate, eguttulate or with several minute apolar guttules.

Culture characteristics—Colonies on PDA reaching up to 70 mm in 7 days, margin regular, covered by felty aerial mycelium, olivaceous, mouse grey towards periphery, reverse dark mouse grey.

Material examined—CHINA, Sichuan Province, Yaan City, Shimian County, 29°13'31" N, 102°21'27" E, alt. 978 m, on leaf spots of *Castanea mollissima*, 10 September 2020, N. Jiang (BJFC-S1792; living culture, CFCC 54343 = SM24); *ibid.* (living culture, SM24B).

Notes—*Didymella* is a famous pathogenic genus mainly occurring on plant leaves [33–37]. Phoma-like species are difficult to identify to the genus and species level due to a lack of good characteristics, making molecular data are essential during species identification [34,35,37]. The new isolates (CFCC 54343 and SM24B) from *Castanea mollissima* grouped with *Didymella coffeae-arabicae* on *Coffea arabica* with high statistical support (Figure A4). Our collection also shared similar morphology in conidial size with *Didymella coffeae-arabicae* [33].

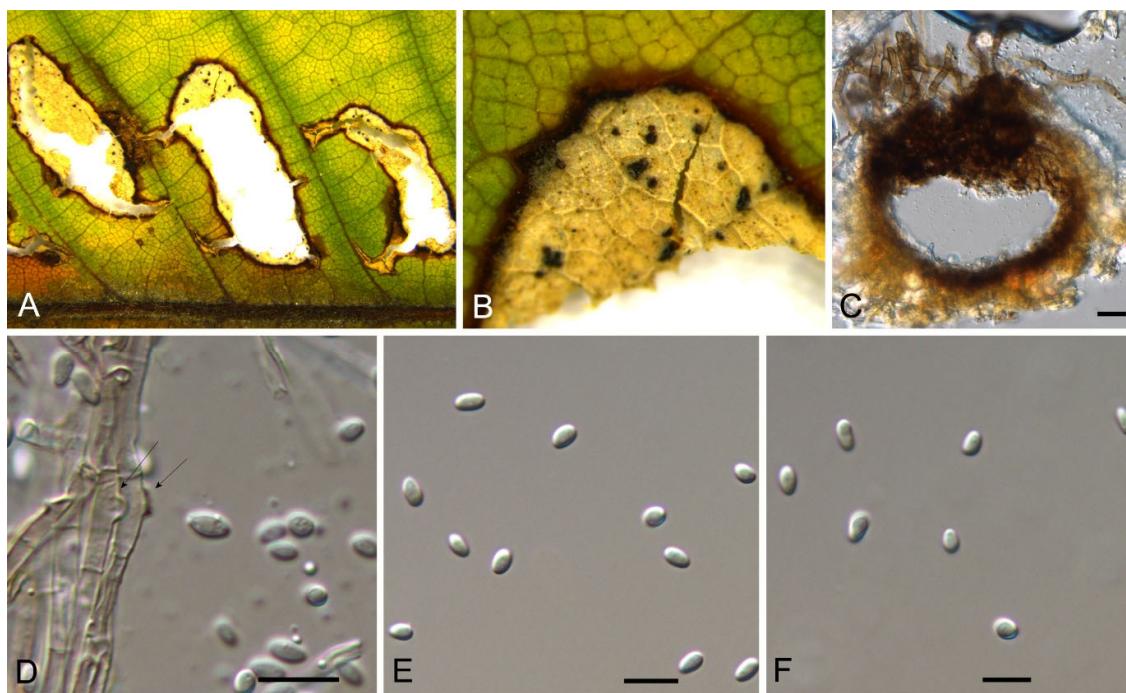

Figure 7. *Didymella coffeee-arabicae* (BJFC-S1792). (A,B) Conidiomata on the diseased leaves of *Castanea mollissima*; (C) Section through the pycnidium; (D) Conidiogenous cells giving rise to conidia (arrows); (E,F) Conidia. Scale bars: C–F = 10 μm .

3.6. *Arthrinium* Kunze

Arthrinium arundinis (Corda) Dyko & B. Sutton, Mycotaxon 8(1): 119 (1979)

Endophytic or pathogenic on *Castanea mollissima* leaves. Sexual morph: Undetermined. Asexual morph was observed on PDA: Mycelium consisting of smooth, hyaline, branched, septate, 1.5–3 μm diam hyphae. Conidiogenous cells 5.5–15 \times 2.5–3.5 μm , aggregated in clusters on hyphae, pale brown, smooth, ampulliform. Conidia 3–4 μm diam. ($\bar{x} = 3.4 \mu\text{m}$, $n = 50$), brown, smooth, globose, with pale equatorial slit.

Culture characteristics—Colonies on PDA reaching up to 70 mm in 7 days, flat, spreading, covered by iron-grey aerial mycelium, reverse grey.

Material examined—CHINA, Hunan Province, Xiangtan City, 27°48'51" N, 112°71'42" E, alt. 85 m, on leaf spots of *Castanea mollissima*, 9 November 2020, N. Jiang (living culture, XT18-1).

Notes—*Arthrinium* is a common genus on a wide range of substrates, including soil, plant debris, plants, lichens, marine algae, and human tissues [38–42]. The new isolate (XT18-1) from *Castanea mollissima* grouped with *A. arundinis* isolates with high statistical support (Figure A5). Therefore, we identify our new isolate as *A. arundinis* and *Castanea mollissima* as a new host record for the fungus.

3.7. *Bartalinia* Tassi

Bartalinia pini F. Liu, L. Cai & Crous, Stud. Mycol. 92: 309 (2019) (Figure 8)

Pathogenic on *Castanea henryi* leaves. Sexual morph: Undetermined. Asexual morph: Conidiomata 85–160 μm diam., 50–120 μm high, acervular, conspicuous, stromatic, scattered or aggregated, rounded, black. Conidiophores reduced to conidiogenous cells, septate, smooth, hyaline, invested in mucus. Conidiogenous cells 4.5–15 \times 1.5–4 μm , annellidic, discrete, ampulliform. Conidia (18.2–)19–21.5(–22.1) \times (3.4–)3.6–4.2(–4.5) μm ($\bar{x} = 20.1 \times 3.8 \mu\text{m}$, $n = 50$), L/W = (4.5–)4.7–5.9(–6.2) ($\bar{x} = 5.3$, $n = 50$), cylindrical with acute or obtuse ends, straight or slightly curved, 4-septate, smooth; basal cell obconic with a truncate base, thin-walled, hyaline, 1.5–3.5 μm long; median cells 3, cylindrical, pale brown, each 3.5–7.5

μm long; apical cell conic with an acute apex, thin-walled, hyaline, 2–3.5 μm long; apical appendage with three branches, tubular, filiform, flexuous, divergent, 5–25 μm long; basal appendage tubular, unbranched, excentric, 3–8 μm long.

Culture characteristics—Colonies on PDA reaching up to 70 mm in 10 days, flat with entire edge, glaucous grey to grey.

Material examined—CHINA, Hunan Province, Changsha City, Changsha County, Jinjing Town, 28°58'52" N, 113°34'38" E, alt. 63 m, on leaf spots of *Castanea henryi*, 10 November 2020, C.M. Tian & N. Jiang (BJFC-S1808; living culture, CFCC 54574 = JJ4).

Notes—*Bartalinia* is morphologically distinct from the other Sporocadaceous genera by its conidial characters [43]. The new isolate (CFCC 54574) from *Castanea henryi* grouped with *B. pini* isolates from *Pinus patula* (Pinaceae) needles and leaves of *Acacia koa* (Fabaceae) (Figure A6) and overlapped in morphology with *B. pini* [43]. Therefore, we identify our new isolate as *B. pini*, China as a new geographical record and *Castanea henryi* as a new host record for the fungus.

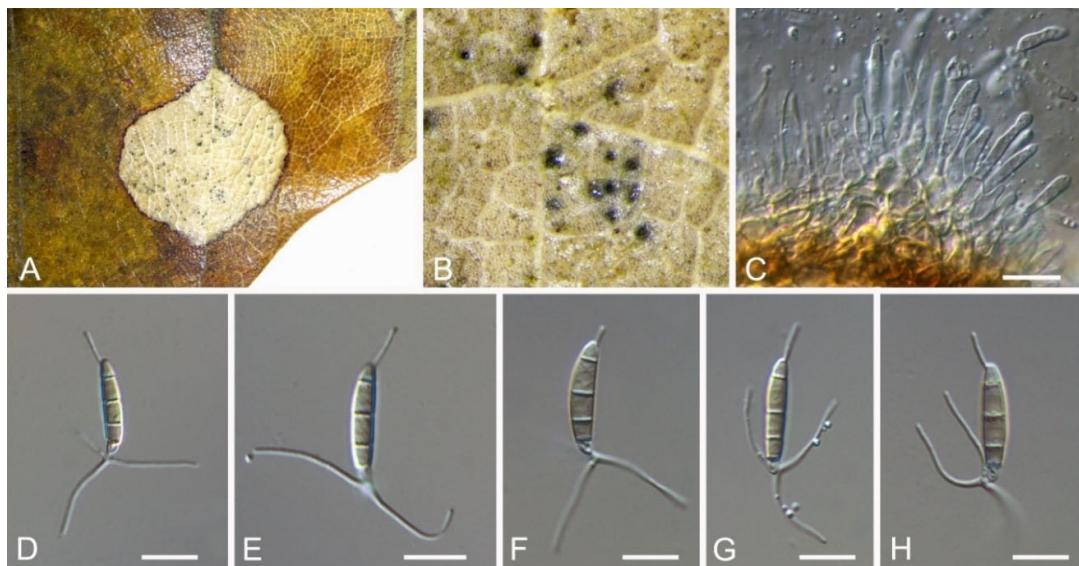

Figure 8. *Bartalinia pini* (BJFC-S1808). (A,B) Conidiomata on the diseased leaves of *Castanea henryi*; (C) Conidiogenous cells giving rise to conidia; (D–H) Conidia. Scale bars: C–F = 10 μm .

3.8. *Discosia* Lib. ex Durieu & Mont.

Discosia castaneae C.M. Tian & N. Jiang, sp. nov. (Figure 10)

Mycobank: MB837794

Etymology—named for the host genus, *Castanea*.

Holotype—BJFC-S1805

Pathogenic on *Castanea mollissima* leaves. Sexual morph: Undetermined. Asexual morph: Conidiomata 100–170 μm diam., 20–40 μm high, acervular, conspicuous, stromatic, scattered or aggregated, rounded, black, glabrous, epidermal. Conidiophores absent. Conidiogenous cells 3–7 \times 1–3 μm , holoblastic to phialidic, ampulliform, integrated, hyaline, smooth-walled. Conidia (14.1–15.4–17(–18.7) \times (2.9–)3.1–3.8(–3.9) μm ($\bar{x} = 16.2 \times 3.5 \mu\text{m}$, $n = 50$), L/W = (3.9–)4.2–5.3(–5.5) ($\bar{x} = 4.8$, $n = 50$), cylindrical to allantoid, initially hyaline, becoming pale brown at maturity, smooth-walled, guttulate, 3-euseptate, slightly constricted at septa, thin-walled; with basal cell obconic, slightly truncate at the base and appendaged; 2 median cells subcylindrical, with second cell from the base 5–8 μm long and third cell 3–6 μm long; apical cell subconical with a obtuse apex; apical and basal cells each with a single, simple, unbranched, filamentous appendage at the ends, apical appendage 5–12 μm and basal appendage 5–10 μm .

Culture characteristics—Colonies on PDA reaching up to 50 mm in 10 days, flat with entire edge, forming concentric circles, olivaceous black, sterile.

Material examined—CHINA, Beijing City, Miyun District, Xinchengzi Town, Potou Village, 40°60'28" N, 117°36'02" E, alt. 65 m, on leaf spots of *Castanea mollissima*, 29 October 2017, C.M. Tian & N. Jiang (BJFC-S1805, holotype; ex-type living cultures, CFCC 54088 = CML1, CML2). Yunnan Province, Zhaotong City, Zhenxiong County, 27°43'28" N, 105°10'35" E, alt. 1280 m, on leaf spots of *Castanea mollissima*, 5 September 2020, N. Jiang (living culture, CFCC 54352 = ZX22A). Hunan Province, Shaoshan City, Yintian Town, 27°52'04" N, 112°35'03" E, alt. 73 m, on leaf spots of *Castanea mollissima*, 9 November 2020, C.M. Tian & N. Jiang (BJFC-S1806, living culture, CFCC 54584 = SS3).

Notes—*Discosia* was recorded on leaf spots of Chinese chestnut leaves in the monograph of chestnut diseases [44]. However, the fungus was not identified to the species level. In present study, we collected *Discosia* samples from Beijing (North China), Hunan and Yunnan (South China), and found it different from any known species [43,45,46]. From the phylogram (Figure 9), *Discosia brasiliensis* was the closest species to *D. castaneae*, but they could be distinguished by their conidial width (3.5–4.5 µm in *D. castaneae* vs. 2–3 µm in *D. brasiliensis*) [46].

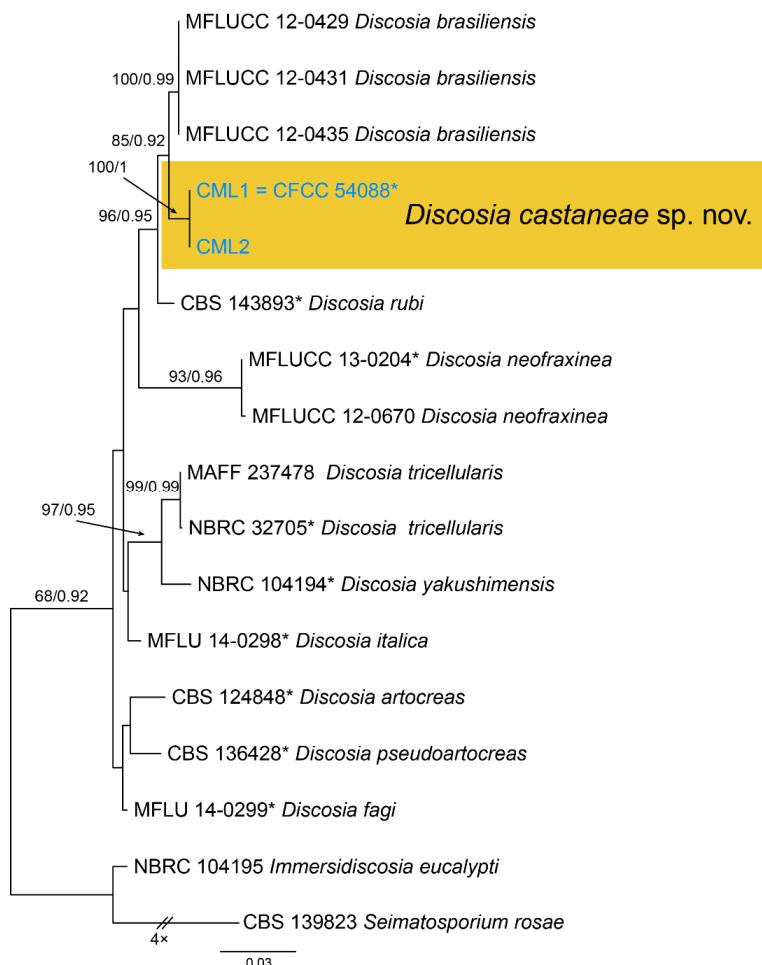

Figure 9. Phylogram generated from RAxML analysis based on combined ITS, LSU and *tub2* sequence data of *Discosia* isolates. The tree was rooted to *Immersidiscosia eucalypti* (CBS 544.95) and *Seimatosporium rosae* (CBS 139823). The scale bar indicates 0.03 nucleotide changes per site. Isolates from this study are marked in blue, ex-type strains are marked with *, and the identified species is marked in yellow.

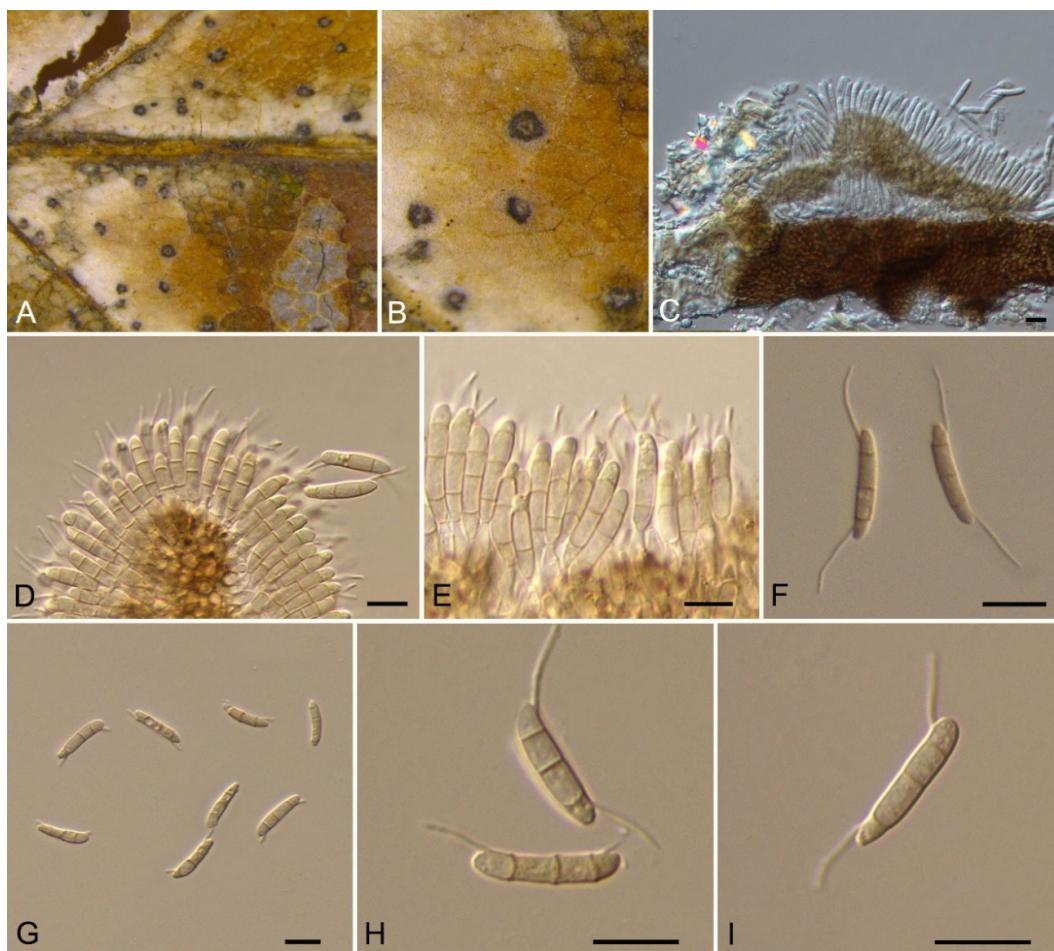

Figure 10. *Discosia castaneae* (BJFC-S1805). (A,B) Conidiomata on the diseased leaves of *Castanea mollissima*; (C) Section through the conidioma; (D,E) Conidiogenous cells giving rise to conidia; (F–I) Conidia. Scale bars: C–I = 10 μ m.

3.9. *Monochaetia* (Sacc.) Allesch.

Monochaetia castaneae C.M. Tian & N. Jiang, sp. nov. (Figure 12)

Mycobank: MB837793

Etymology—named for the host genus, *Castanea*.

Holotype—BJFC-S1807

Pathogenic on *Castanea mollissima* leaves. Sexual morph: Undetermined. Asexual morph: Conidiomata 120–230 μ m diam., 20–50 μ m high, acervular, conspicuous, scattered or aggregated, rounded, black. Conidiophores cylindrical, hyaline, smooth-walled. Conidiogenous cells 12–20 \times 1.5–2.5 μ m, phialidic, ampulliform, discrete, hyaline, smooth-walled. Conidia (18.8–)20–24(–27.3) \times (4.7–)5.4–6.2(–6.6) μ m (\bar{x} = 22 \times 5.8 μ m, n = 50), L/W = (3.1–)3.2–4.5(–5.8) (\bar{x} = 3.8, n = 50), fusiform, tapering at both ends, 4-septate; basal cell 2.5–4.0 μ m long, conic, hyaline and smooth-walled; three median cells each 3.5–5.5 μ m long, doliform, light brown, rough-walled; apical cell 3.0–4.5 μ m long, conic, hyaline and smooth-walled; apical appendage 17.5–35 μ m long, single, tubular, filiform; basal appendage 10–20 μ m long, single, central, tubular, filiform.

Culture characteristics—Colonies on PDA reaching up to 40 mm in 15 days, flat, spreading, with sparse aerial mycelium and smooth, lobate margin, cinnamon, reverse isabelline. Fruiting bodies were observed after 20 days.

Material examined—CHINA, Sichuan Province, Yaan City, Shimian County, 29°13'31" N, 102°21'27" E, alt. 978 m, on leaf spots of *Castanea mollissima*, 10 September

2020, N. Jiang (BJFC-S1807, holotype; ex-type living cultures, CFCC 54354 = SM9-1, SM9-2).

Notes—*Monochaetia concentrica* and *M. kansensis* were recorded to inhabit *Castanea* leaves, but *Monochaetia castaneae* from present study is narrower than them (4.7–6.6 µm in *M. castaneae* vs. 6.5–8.5 µm in *M. concentrica* vs. 6.0–8.0 µm in *M. kansensis*) [47]. *Monochaetia castaneae* is phylogenetically close to *M. junipericola* from twigs of *Juniperus communis* (Figure 11), but they are distinguished by hosts and conidial sizes (18.8–27.3 × 4.7–6.6 µm in *M. castaneae* vs. 22–28 × 5.0–7.0 µm in *M. junipericola*) [48].

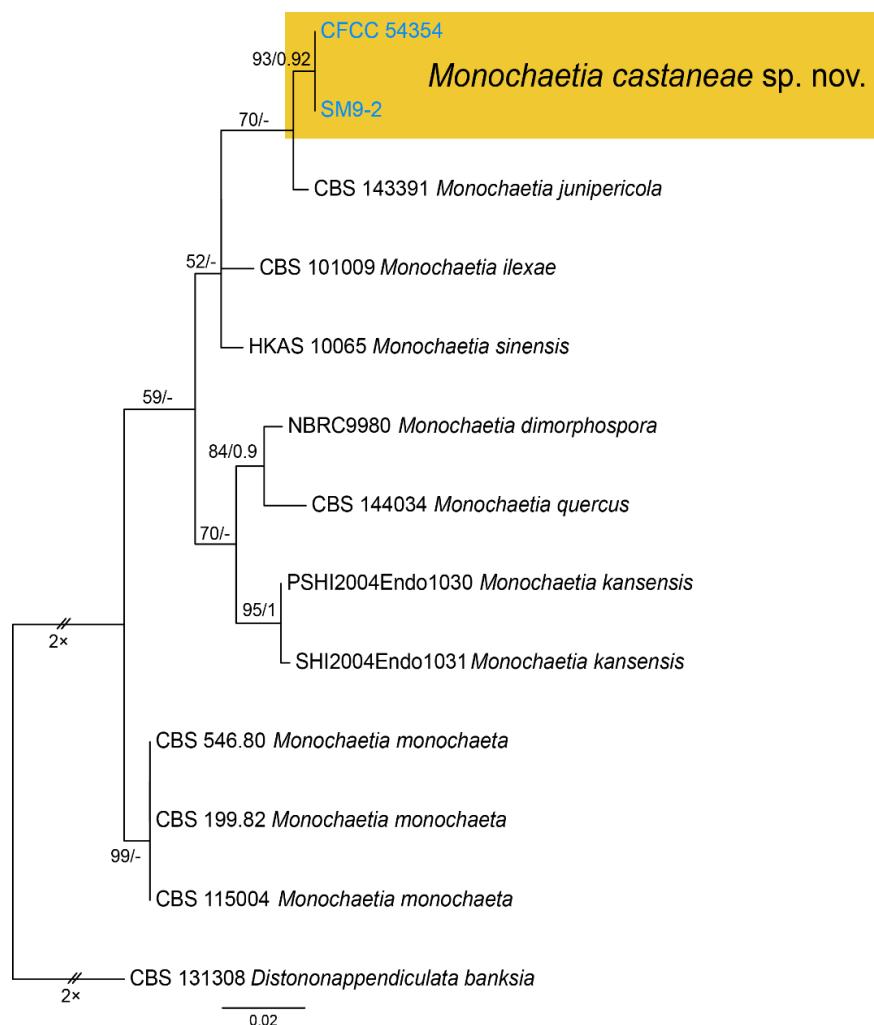

Figure 11. Phylogram generated from RAxML analysis based on combined ITS sequence data of *Monochaetia* isolates. The tree was rooted to *Distiononappendiculata banksia* (CBS 131308). The scale bar indicates 0.02 nucleotide changes per site. Isolates from this study are highlighted. Isolates from this study are marked in blue, and the identified species is marked in yellow.

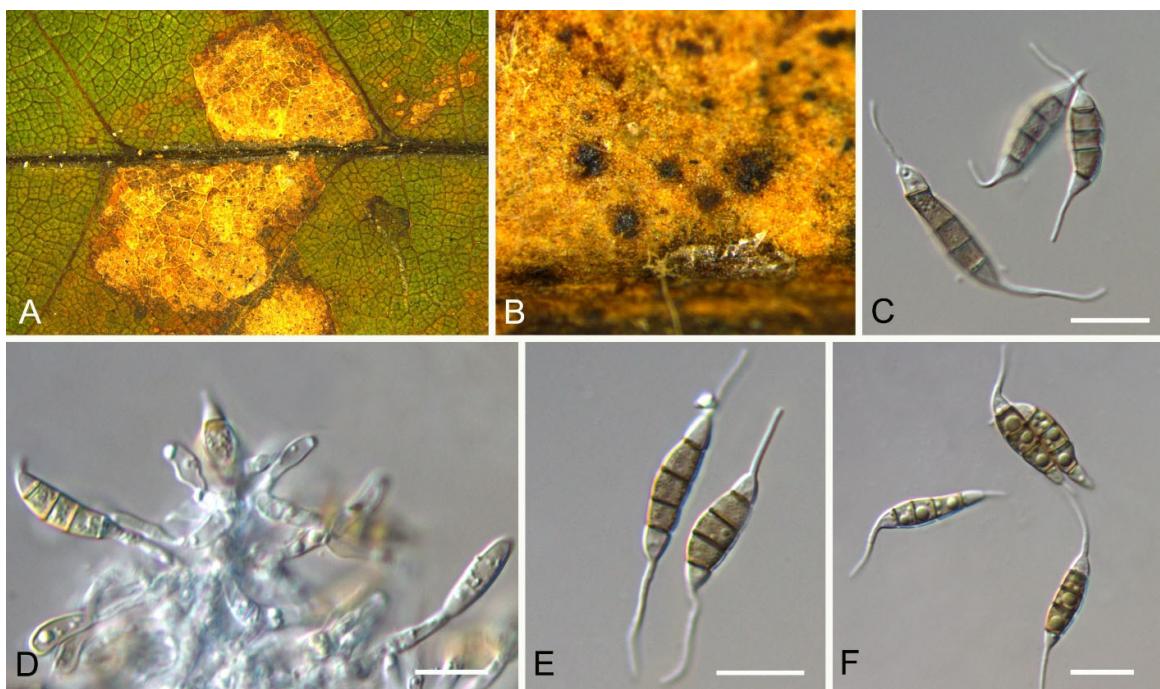

Figure 12. *Monochaetia castaneae* (BJFC-S1807). (A,B) Conidiomata on the diseased leaves of *Castanea mollissima*; (C,F) Conidia; (D) Conidiogenous cells giving rise to conidia. Scale bars: C–F = 10 μ m.

3.10. *Neopestalotiopsis* Maharachch., K.D. Hyde & Crous

Neopestalotiopsis asiatica Maharachch., K.D. Hyde & Crous, Stud. Mycol. 79: 136 (2014) (Figure 14)

Pathogenic on *Castanea mollissima* leaves. Sexual morph: Undetermined. Asexual morph: Conidiomata 80–200 μ m diam., 20–150 μ m high, acervular, conspicuous, scattered or aggregated, rounded, black. Conidiophores reduced to conidiogenous cells, smooth, hyaline. Conidiogenous cells 4–10 \times 1.5–4 μ m, discrete, thin-walled, lageniform, subcylindrical or irregular. Conidia (15.4–)17.6–23.1(–25.5) \times (4.6–)5.4–7.8(–8.4) μ m (\bar{x} = 19.4 \times 6.2 μ m, n = 50), L/W = (2.2–)2.7–3.5(–4) (\bar{x} = 3.1, n = 50), basal cell conic to obconic with a truncate base, hyaline, minutely verruculose and thin-walled, 4–5.5 μ m long; three median cells doliiform, versicolourous, second cell from base pale brown to olivaceous, 4.5–6 μ m long; third cell honey brown, 5–6.5 μ m long; fourth cell brown, 4.5–5.5 μ m long; apical cell 3.5–5 μ m long, hyaline, subcylindrical, rugose and thin-walled; with 3 (seldom 4) tubular apical appendages, arising from the apical crest, unbranched, filiform, 23–35 μ m long; basal appendage present, 3.5–8.5 μ m long.

Culture characteristics—Colonies on PDA reaching up to 60 mm in 10 days, dense aerial mycelium on the surface with undulate edge, white. Fruiting bodies were observed after 20 days.

Material examined—CHINA, Sichuan Province, Yaan City, Shimian County, 29°13'31" N, 102°21'27" E, alt. 978 m, on leaf spots of *Castanea mollissima*, 10 September 2020, N. Jiang (BJFC-S1789, living culture, CFCC 54339 = SM32); *ibid.* (living cultures, SM7, SM8B, SM11, SM19B).

Notes—*Neopestalotiopsis asiatica* was described based on the endophytic isolate from unknown trees in China under the name of *Pestalotiopsis asiatica* [49], but subsequently transferred to the genus *Neopestalotiopsis* [50]. In the present study, several isolates of *N. asiatica* were obtained from Chinese chestnut diseased leaves (Figure 13).

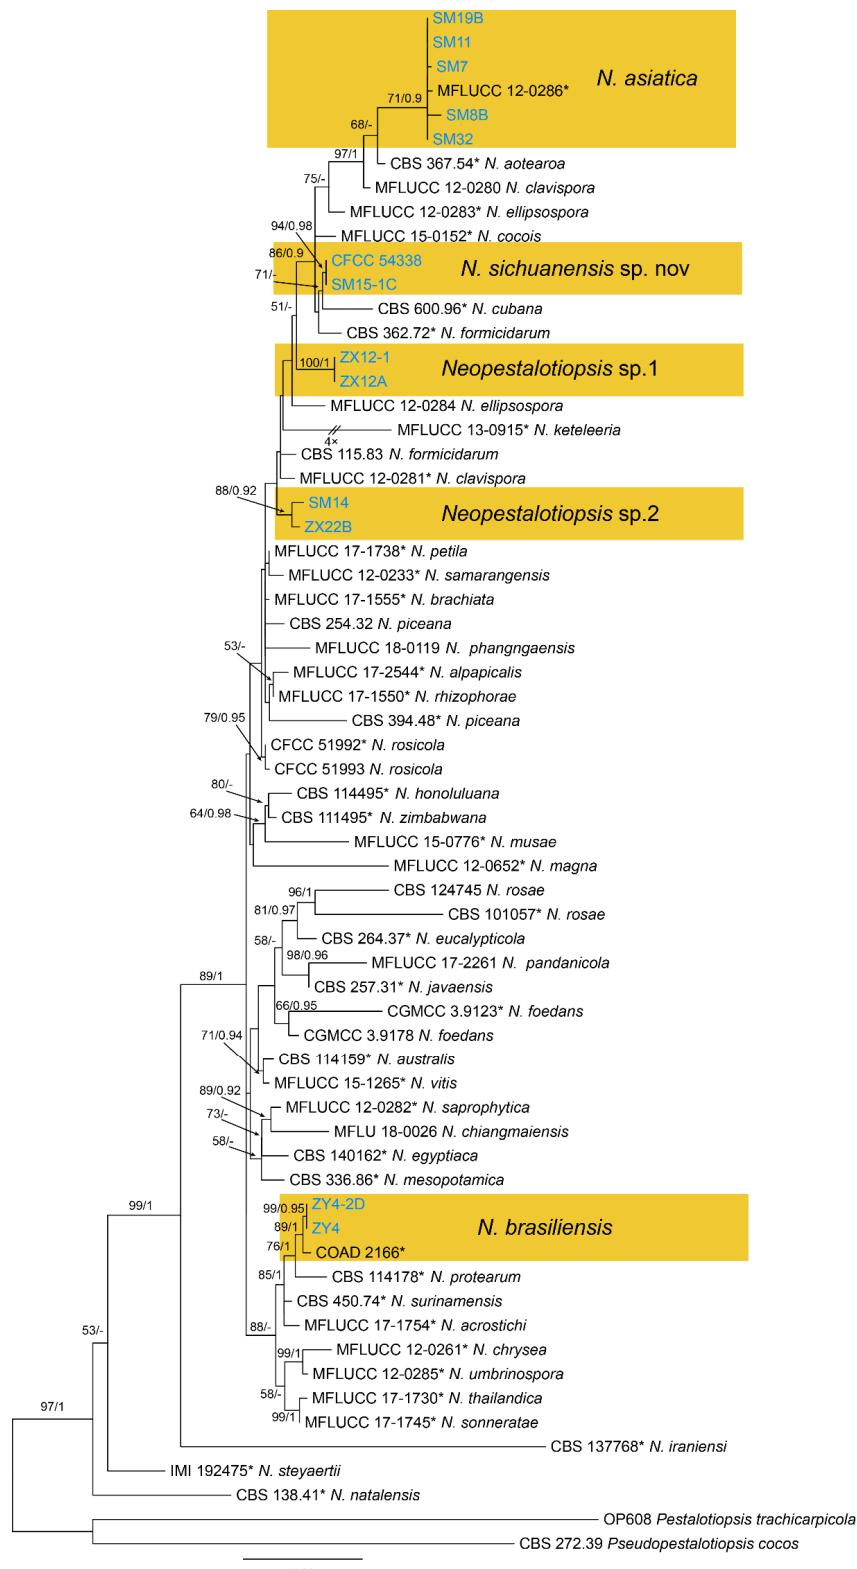

Figure 13. Phylogram generated from RAxML analysis based on combined ITS *tef1* and *tub2* sequence data of *Neopestalotiopsis* isolates. The tree was rooted to *Pestalotiopsis trachicarpicola* (OP608) and *Pseudopestalotiopsis cocos* (CBS 272.39). The scale bar indicates 0.02 nucleotide changes per site. Isolates from this study are marked in blue, ex-type strains are marked with *, and the identified species are marked in yellow.

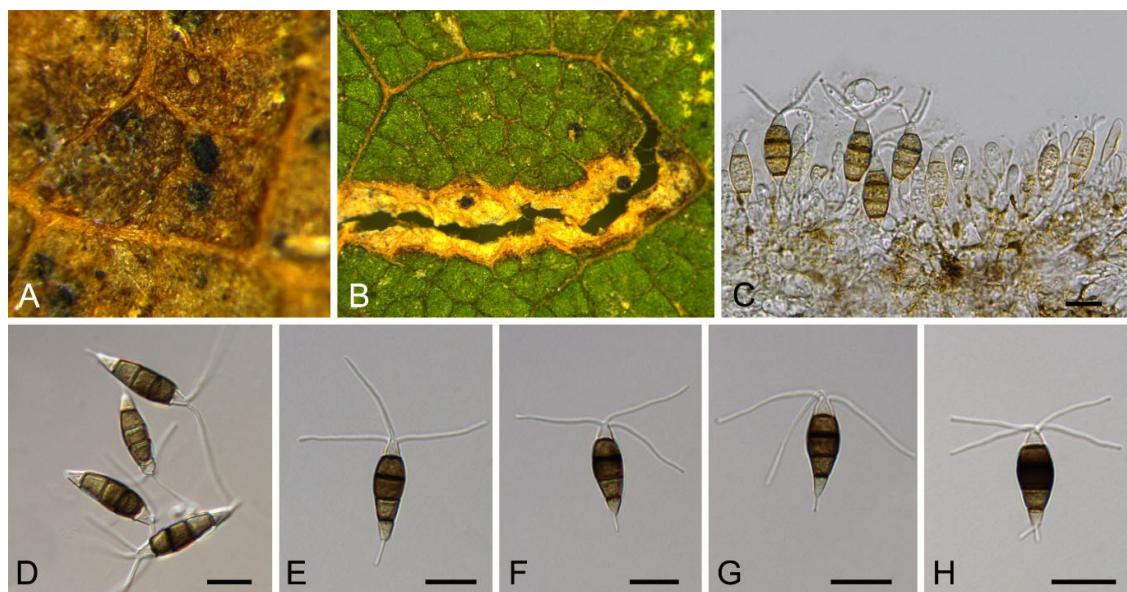

Figure 14. *Neopestalotiopsis asiatica* (BJFC-S1789). (A,B) Conidiomata on the diseased leaves of *Castanea mollissima*; (C) Co-nidiogenous cells giving rise to conidia; (D–H) Conidia. Scale bars: C–H = 10 μ m.

3.10.1. *Neopestalotiopsis brasiliensis*

Neopestalotiopsis brasiliensis V.P. Abreu, A.W.C. Rosado & O.L. Pereira, Acta Bot. Brasiliaca 32(4): 661 (2018) (Figure 15)

Pathogenic on *Castanea mollissima* leaves. Sexual morph: Undetermined. Asexual morph: Conidiomata 50–150 μ m diam., 30–90 μ m high, acervular, conspicuous, scattered or aggregated, rounded, black. Conidiophores reduced to conidiogenous cells, smooth, hyaline. Conidiogenous cells 6–15 \times 1.5–3.5 μ m, discrete, thin-walled, lageniform, subcylindrical or irregular. Conidia (18.5–)19.5–24.1(–26.1) \times (5–)5.3–6.4(–6.8) μ m (\bar{x} = 21.8 \times 5.9 μ m, n = 50), L/W = (2.9–)3.2–4.3(–4.4) (\bar{x} = 3.8, n = 50), fusoid, ellipsoid to subcylindrical, straight to slightly curved, 4-septate; basal cell conic to obconic with a truncate base, hyaline, minutely verruculose and thin-walled, 3–5.5 μ m long; three median cells doliiform, versicolourous, second cell from base pale brown to olivaceous, 4–6.5 μ m long; third cell honey brown, 4.5–5.5 μ m long; fourth cell brown, 4.5–6 μ m long; apical cell 3.5–5.5 μ m long, hyaline, subcylindrical, rugose and thin-walled; with 2 (seldom 3) tubular apical appendages, arising from the apical crest, unbranched, filiform, 8–20 μ m long; basal appendage present, 2–5.5 μ m long.

Culture characteristics—Colonies on PDA reaching up to 60 mm in 7 days, dense aerial mycelium on the surface with undulate edge, white. Fruiting bodies were observed after 15 days.

Material examined—CHINA, Guizhou Province, Zunyi City, Goujiang Town, 27°24'49" N, 106°52'49" E, alt. 1064 m, on leaf spots of *Castanea mollissima*, 7 September 2020, N. Jiang (BJFC-S1791, living culture, CFCC 54341 = ZY4); *ibid.* (living culture, ZY4-2D).

Notes—*Neopestalotiopsis brasiliensis* was described from rotted fruits of *Psidium guajava* in Brazil [51]. In present study, strains from diseased chestnut leaves formed a supported clade with the ex-type strain COAD 2166 (Figure 13), and shared similar morphology. Hence, we identified our strains as *N. brasiliensis*, which represented a new host and geographical record.

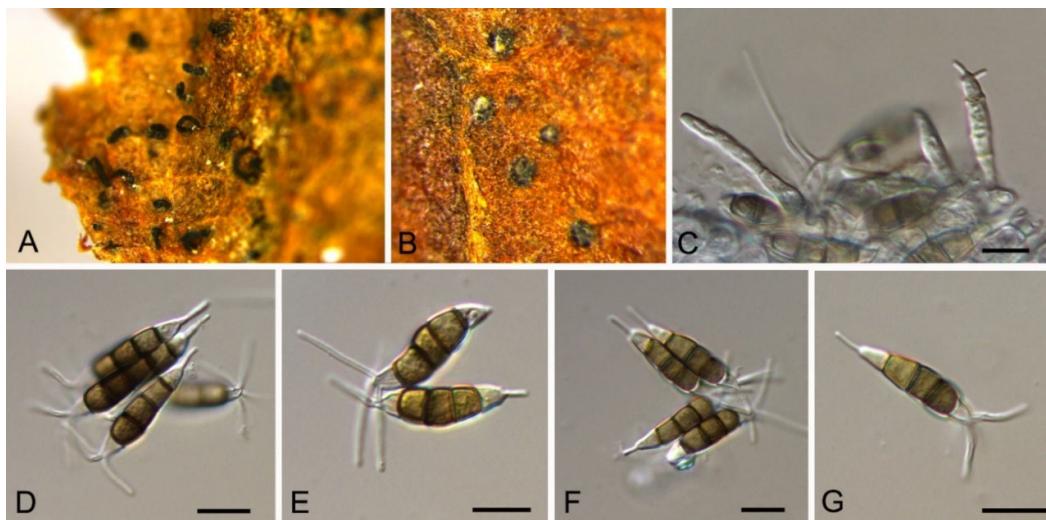

Figure 15. *Neopestalotiopsis brasiliensis* (BJFC-S1791). (A,B) Conidiomata on the diseased leaves of *Castanea mollissima*; (C) Conidiogenous cells giving rise to conidia; (D–G) Conidia. Scale bars: C–G = 10 μm .

3.10.2. *Neopestalotiopsis sichuanensis*

C.M. Tian & N. Jiang, sp. nov. (Figure 16)

Mycobank: MB 837792

Etymology—named for the location of the type specimen.

Holotype—BJFC-S1788

Pathogenic on *Castanea mollissima* leaves. Sexual morph: Undetermined. Asexual morph: Conidiomata 100–250 μm diam., 50–150 μm high, acervular, conspicuous, scattered or aggregated, rounded, black. Conidiophores reduced to conidiogenous cells, smooth, hyaline. Conidiogenous cells 7–20 \times 2–6 μm , discrete, thin-walled, lageniform, subcylindrical or irregular. Conidia (23.2–)24.3–30.4(–32.8) \times (5.7–)6.3–7.1(–7.5) μm (\bar{x} = 27.3 \times 6.7 μm , n = 50), L/W = (3.4–)3.5–4.6(–5.1) (\bar{x} = 4.1, n = 50), fusoid, ellipsoid to subcylindrical, straight to slightly curved, 4-septate; basal cell conic to obconic with a truncate base, hyaline, minutely verruculose and thin-walled, 3.5–5 μm long; three median cells doliform, versicolourous, second cell from base pale brown to olivaceous, 3.5–6 μm long; third cell honey brown, 4.5–6.5 μm long; fourth cell brown, 4.5–6 μm long; apical cell 3.5–6 μm long, hyaline, subcylindrical, rugose and thin-walled; with 2 or 3 tubular apical appendages, arising from the apical crest, unbranched, filiform, 8–15 μm long; basal appendage present, 1.5–4 μm long.

Culture characteristics—Colonies on PDA reaching up to 60 mm in 7 days, dense aerial mycelium on the surface with undulate edge, white. Fruiting bodies were observed after 15 days.

Material examined—CHINA, Sichuan Province, Yaan City, Shimian County, 29°13'31" N, 102°21'27" E, alt. 978 m, on leaf spots of *Castanea mollissima*, 10 September 2020, N. Jiang (BJFC-S1788, holotype; ex-type living culture, CFCC 54338 = SM15-1); *ibid.* (living culture, SM15-1C).

Notes—*Neopestalotiopsis sichuanensis* was phylogenetically close to *N. cubana* (Figure 13) but differed in conidial width (5.7–7.5 μm in *N. sichuanensis* vs. 7.5–10 μm in *N. cubana*) [50].

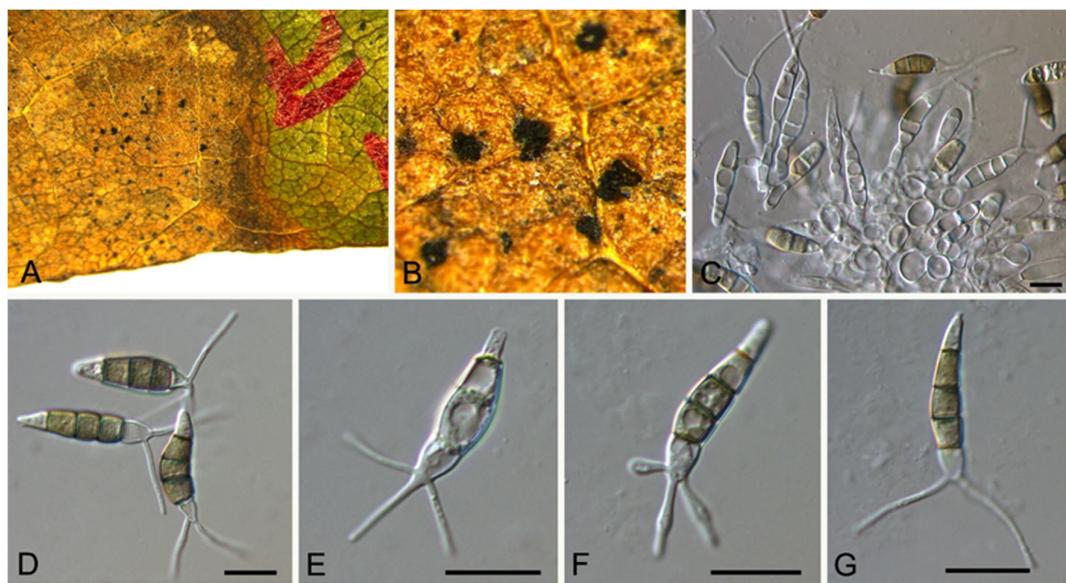

Figure 16. *Neopestalotiopsis sichuanensis* (BJFC-S1788). (A,B) Conidiomata on the diseased leaves of *Castanea mollissima*; (C) Conidiogenous cells giving rise to conidia; (D–G) Conidia. Scale bars: C–G = 10 μm .

3.10.3. *Neopestalotiopsis* sp.1

Pathogenic on *Castanea mollissima* leaves. Sexual morph: Undetermined. Asexual morph: Conidiomata 80–150 μm diam., 30–60 μm high, acervular, conspicuous, scattered or aggregated, rounded, black. Conidiophores reduced to conidiogenous cells, smooth, hyaline. Conidiogenous cells 5.5–15.5 \times 3–7 μm , discrete, thin-walled, lageniform, subcylindrical or irregular. Conidia (19.1–)19.9–23.2(–24.7) \times (5.4–)5.8–7.6(–8.6) μm ($\bar{x} = 21.6 \times 6.7 \mu\text{m}$, $n = 50$), L/W = (2.9–)3.0–3.5(–3.7) ($\bar{x} = 3.2$, $n = 50$), fusoid, ellipsoid to subcylindrical, straight to slightly curved, 4-septate; basal cell conic to obconic with a truncate base, hyaline, minutely verruculose and thin-walled, 3–4.5 μm long; three median cells doliiform, versicolourous, second cell from base pale brown to olivaceous, 3–5 μm long; third cell honey brown, 4.5–6 μm long; fourth cell brown, 4–6 μm long; apical cell 3.5–5 μm long, hyaline, subcylindrical, rugose and thin-walled; with 2 or 3 tubular apical appendages, arising from the apical crest, unbranched, filiform, 7.5–14 μm long; basal appendage present, 3–6.5 μm long (Figure 17).

Culture characteristics—Colonies on PDA reaching up to 60 mm in 7 days, dense aerial mycelium on the surface with undulate edge, white. Fruiting bodies were observed after 15 days.

Material examined—CHINA, Yunnan Province, Zhaotong City, Zhenxiong County, 27°43'28" N, 105°10'35" E, alt. 1280 m, on leaf spots of *Castanea mollissima*, 5 September 2020, N. Jiang (BJFC-S1787, living culture, CFCC 54337 = ZX12A); *ibid.* (living culture, ZX12-1).

Notes—Although phylogenetically distinct, these two isolates were not proposed as a new species for lack of distinguished characters from close clades (Figure 13).

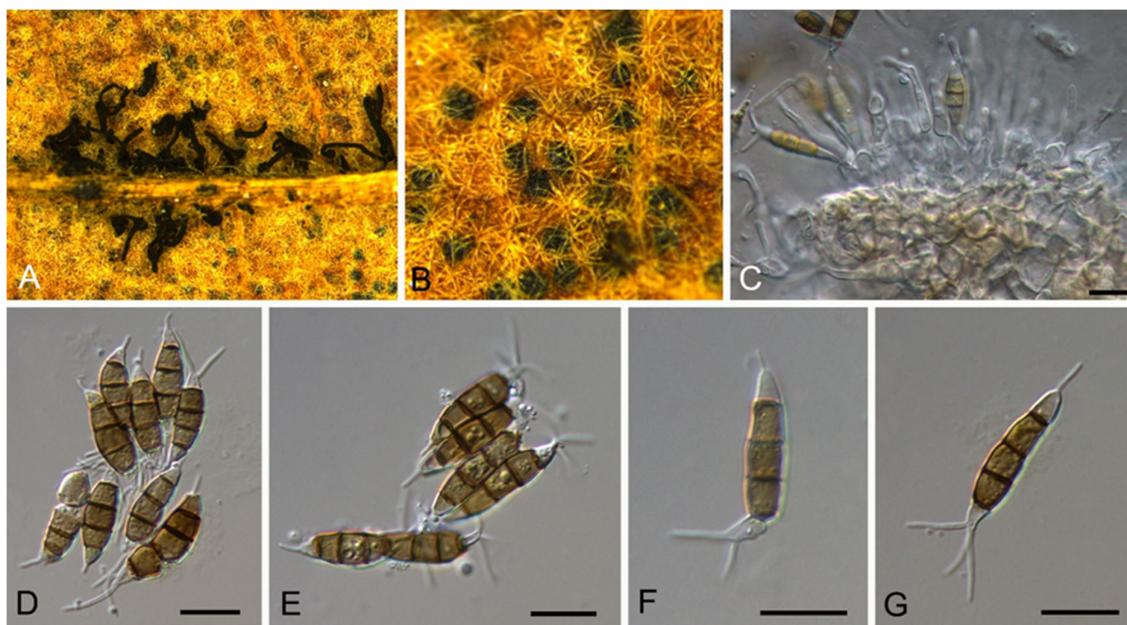

Figure 17. *Neopestalotiopsis* sp.1 (BJFC-S1787). (A,B) Conidiomata on the diseased leaves of *Castanea mollissima*; (C) Conidiogenous cells giving rise to conidia; (D–G) Conidia. Scale bars: C–G = 10 μ m.

3.10.4. *Neopestalotiopsis* sp.2

Pathogenic on *Castanea mollissima* leaves. Sexual morph: Undetermined. Asexual morph: Conidiomata 75–175 μ m diam., 30–75 μ m high, acervular, conspicuous, scattered or aggregated, rounded, black. Conidiophores reduced to conidiogenous cells, smooth, hyaline. Conidiogenous cells 3.5–8 \times 2.5–5.5 μ m, discrete, thin-walled, lageniform, subcylindrical or irregular. Conidia (21.4–)22–25.2(–26.2) \times (5.1–)6.2–7.7(–8.7) μ m (\bar{x} = 23.6 \times 7 μ m, n = 50), L/W = (2.9–)3–3.9(–4.4) (\bar{x} = 3.4, n = 50), fusoid, ellipsoid to subcylindrical, straight to slightly curved, 4-septate; basal cell conic to obconic with a truncate base, hyaline, minutely verruculose and thin-walled, 3–5 μ m long; three median cells doliiform, versicolourous, second cell from base pale brown to olivaceous, 4.5–6.5 μ m long; third cell honey brown, 4.5–6 μ m long; fourth cell brown, 4–6 μ m long; apical cell 3.5–5 μ m long, hyaline, subcylindrical, rugose and thin-walled; with 2 (seldom 3) tubular apical appendages, arising from the apical crest, unbranched, filiform, 10–25 μ m long; basal appendage present, 1.5–5 μ m long (Figure 18).

Culture characteristics—Colonies on PDA reaching up to 60 mm in 7 days, dense aerial mycelium on the surface with undulate edge, white. Fruiting bodies were observed after 15 days.

Material examined—CHINA, Sichuan Province, Yaan City, Shimian County, 29°13'31" N, 102°21'27" E, alt. 978 m, on leaf spots of *Castanea mollissima*, 10 September 2020, N. Jiang (BJFC-S1790, living culture, CFCC 54340 = SM14); Yunnan Province, Zhaotong City, Zhenxiong County, 27°43'28" N, 105°10'35" E, alt. 1280 m, on leaf spots of *Castanea mollissima*, 5 September 2020, N. Jiang (living culture, ZX22B).

Notes—Although phylogenetically distinct, these two isolates were not proposed as a new species for lack of distinguished characters from close clades (Figure 13).

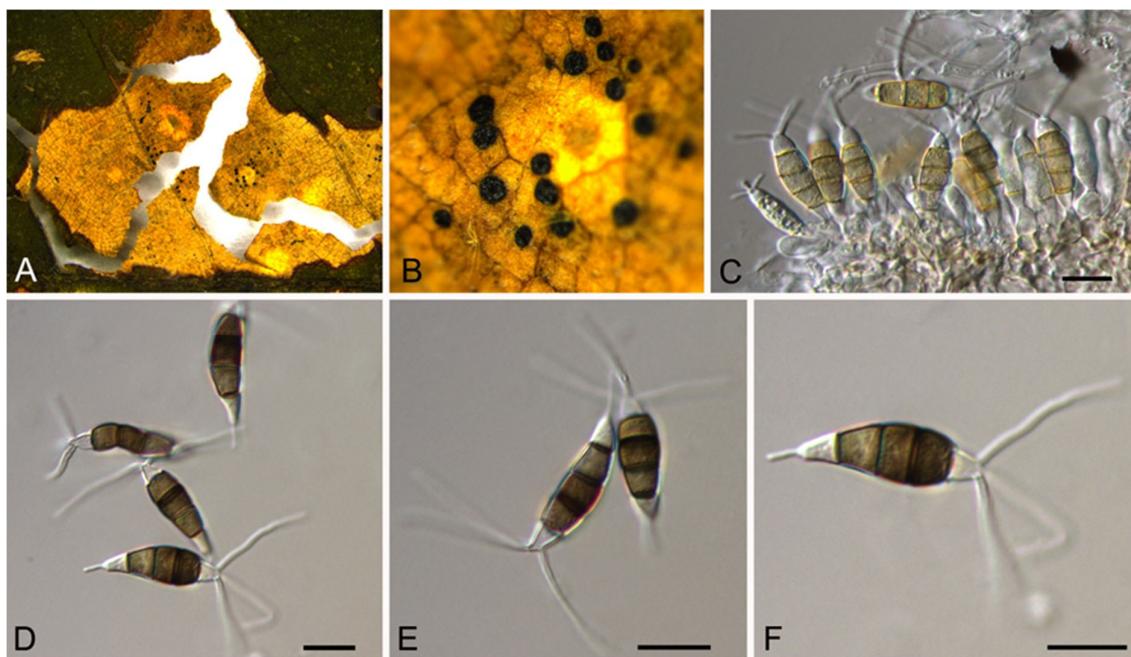

Figure 18. *Neopestalotiopsis* sp.2 (BJFC-S1790). (A,B) Conidiomata on the diseased leaves of *Castanea mollissima*; (C) Conidiogenous cells giving rise to conidia; (D–F) Conidia. Scale bars: C–F = 10 μ m.

3.11. Pestalotiopsis Steyaert

Pestalotiopsis kenyana Maharachch., K.D. Hyde & Crous, Stud. Mycol. 79: 166 (2014) (Figure 19)

Pathogenic on *Castanea henryi* and *C. mollissima* leaves. Sexual morph: Undetermined. Asexual morph: Conidiomata 50–250 μ m diam., 30–150 μ m high, acervular, conspicuous, scattered or aggregated, rounded, black. Conidiophores reduced to conidiogenous cells, smooth, hyaline. Conidiogenous cells 5–19 \times 2.5–6.5 μ m, discrete, thin-walled, lageniform, subcylindrical or irregular. Conidia (20.4–)21.8–26.2(–28) \times (6.1–)6.3–7.4(–8) μ m (\bar{x} = 23.8 \times 6.9 μ m, n = 50), L/W = (3–)3.1–3.9(–4.2) (\bar{x} = 3.5, n = 50), fusoid, ellipsoid to subcylindrical, straight to slightly curved, 4-septate; basal cell conic to obconic with a truncate base, hyaline, minutely verruculose and thin-walled, 3–5 μ m long; three median cells doliiform, concolourous, brown, second cell 3–5.5 μ m long; third cell 4.5–6.5 μ m long; fourth cell 4.5–6 μ m long; apical cell 3.5–5.5 μ m long, hyaline, subcylindrical, rugose and thin-walled; with 3 tubular apical appendages, arising from the apical crest, unbranched, filiform, 3.5–15 μ m long; basal appendage present, 1.5–3.5 μ m long.

Culture characteristics—Colonies on PDA reaching up to 60 mm in 7 days, dense aerial mycelium on the surface with undulate edge, white. Fruiting bodies were observed after 15 days.

Material examined—CHINA, Yunnan Province, Zhaotong City, Zhenxiong County, 27°43'28" N, 105°10'35" E, alt. 1280 m, on leaf spots of *Castanea mollissima*, 5 September 2020, N. Jiang (BJFC-S1784, living culture, CFCC 54336 = ZX11); *ibid.* (living culture, ZX3, ZX7, ZX9, ZX18A); Guizhou Province, Zunyi City, Goujiang Town, 27°24'49" N, 106°52'49" E, alt. 1064 m, on leaf spots of *Castanea mollissima*, 7 September 2020, N. Jiang (BJFC-S1786, living culture, ZY6-2A); *ibid.* (living culture, ZY7); Sichuan Province, Yaan City, Shimian County, 29°13'31" N, 102°21'27" E, alt. 978 m, on leaf spots of *Castanea mollissima*, 10 September 2020, N. Jiang (BJFC-S1785, living culture, SM18); Hunan Province, Changsha City, Changsha County, Jinjing Town, 28°58'52" N, 113°34'38" E, alt. 63 m, on leaf spots of *Castanea henryi*, 10 November 2020, C.M. Tian & N. Jiang (BJFC-S1817; living culture, JJ 2A); *ibid.* (living cultures, JJ5, JJ10, JJ13, JJ15, JJ17, JJ18, JJ26).

Notes—*Pestalotiopsis kenyana* was proposed from *Coffea* sp. in Kenya [50]. Strains collected from *Castanea mollissima* in present study formed a supported clade with *Pestalotiopsis kenyana* (Figure A7), and shared similar morphology. Hence, we identified our strains as *P. kenyana*, which represented a new host record.

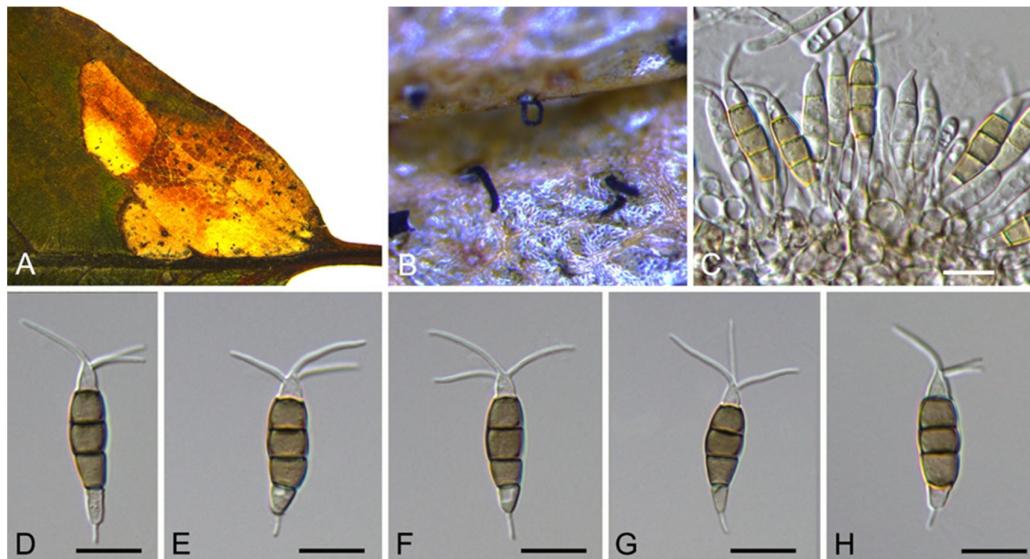

Figure 19. *Pestalotiopsis kenyana* (BJFC-S1784). (A,B) Conidiomata on the diseased leaves of *Castanea mollissima*; (C) Conidiogenous cells giving rise to conidia; (D–H) Conidia. Scale bars: C–H = 10 μ m.

3.12. *Robillarda* Sacc.

Robillarda sessilis (Sacc.) Sacc., *Michelia* 2(no. 6): 8 (1880) (Figure 20)

Pathogenic on *Castanea mollissima* leaves. Sexual morph: Undetermined. Asexual morph: Conidiomata 100–200 μ m diam., 20–60 μ m high, acervular, conspicuous, scattered or aggregated, rounded, black. Conidiophores reduced to conidiogenous cells, smooth, hyaline. Conidiogenous cells 2.5–6 \times 1.5–3 μ m, discrete, thin-walled, guttulate or not, lageniform, ampulliform or irregular. Conidia composed of a 1-septate conidium body and a septate apical cell modified into a branched appendage. Conidium body (10.7–)11.2–13.1(–13.5) \times (2.9–)3.1–3.8(–3.9) μ m (\bar{x} = 12.2 \times 3.4 μ m, n = 50), L/W = (2.9–)3.1–4.1(–4.5) (\bar{x} = 3.6, n = 50), cylindrical, straight, 1-septate, smooth, hyaline to pale brown, guttulate, slightly constricted at the median septum; apical cell cylindrical for 4.0–5.0 μ m long, then dividing into 2–4 (mostly 3) divergent branches; apical appendages unbranched, attenuated, 15–28 μ m long; basal appendages absent.

Culture characteristics—Colonies on PDA reaching up to 60 mm in 15 days, flat with entire edge, white, aerial mycelia villiform. Fruiting bodies were observed after 20 days.

Material examined—CHINA, Yunnan Province, Zhaotong City, Zhenxiong County, 27°43'28" N, 105°10'35" E, alt. 1280 m, on leaf spots of *Castanea mollissima*, 5 September 2020, N. Jiang (BJFC-S1804, living culture, CFCC 54353 = ZX5); *ibid.* (living culture, ZX5-1); Guizhou Province, Zunyi City, Goujiang Town, 27°24'49" N, 106°52'49" E, alt. 1064 m, on leaf spots of *Castanea mollissima*, 7 September 2020, N. Jiang (living culture, ZY5-1).

Notes—*Robillarda sessilis* was documented from quite variable hosts, such as *Bischofia*, *Cocos*, *Ficus*, *Fragaria*, *Fumana*, *Ludwigia*, *Magnolia*, *Paeonia*, *Quercus*, *Randia*, *Rosa*, *Rubus*, and *Vitis* [52]. Strains from present study clustered with the ex-epitype strain (CBS 114312) of *Robillarda sessilis* (Figure A8). This is the first report of this fungus on the host *Castanea mollissima*, and in China as a country.

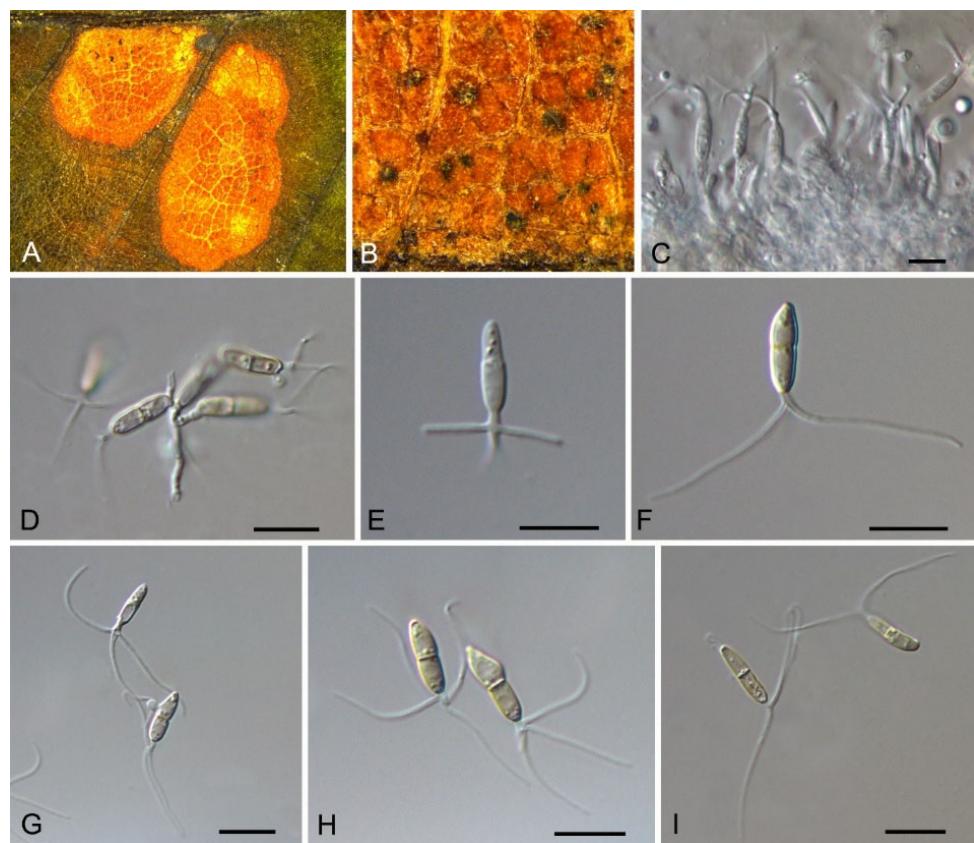

Figure 20. *Robillarda sessilis* (BJFC-S1804). (A,B) Conidiomata on the diseased leaves of *Castanea mollissima*; (C,D) Conidiogenous cells giving rise to conidia; (E–I) Conidia. Scale bars: C–I = 10 μ m.

3.13. *Diaporthe* Nitschke

Diaporthe lithocarpi Y.H. Gao & L. Cai, Fungal Biology 119(5): 306 (2015) (Figure 21)

Pathogenic on *Castanea henryi* leaves. Sexual morph: Undetermined. Asexual morph: Conidiomata 120–3000 μ m diam., pycnidial, aggregated, globose to subglobose, black. Conidiophores reduced to conidiogenous cells. Conidiogenous cells 2.5–12.5 \times 1.5–3 μ m, cylindrical, hyaline, phialidic, unbranched, straight. Conidia (7.6–)7.9–9.1(–9.8) \times (2.5–)2.6–3(–3.1) μ m (\bar{x} = 8.5 \times 2.8 μ m, n = 50), L/W = (2.4–)2.7–3.4(–3.7) (\bar{x} = 3.1, n = 50), aseptate, hyaline, ellipsoidal, biguttulate, mostly with one end obtuse and the other acute.

Culture characteristics—Colonies on PDA reaching up to 60 mm in 7 days, flat, initially white mycelium, gradually becoming pale brownish, with cottony aerial mycelium and fringed margin; reverse pale yellowish.

Material examined—CHINA, Hunan Province, Changsha City, Changsha County, Jinjing Town, 28°58'52" N, 113°34'38" E, alt. 63 m, on leaf spots of *Castanea henryi*, 10 November 2020, C.M. Tian & N. Jiang (BJFC-S1809; living culture, CFCC 54573 = JJ3); *ibid.* (living cultures, JJ3-2, JJ26B).

Notes—*Diaporthe lithocarpi* was reported to cause leaf spots on *Lithocarpus glabra*, *Lopetatum chinensis*, *Smilax china*, *S. glabra* and *Ternstroemia gymnanthera* in Zhejiang Province of China [53]. The present study adds a new *Castanea henryi* host for the fungus based on the phylogenetic inference of ITS, *cal*, *his*, *tef1* and *tub2* sequence data (Figure A9), and exactly matched morphology.

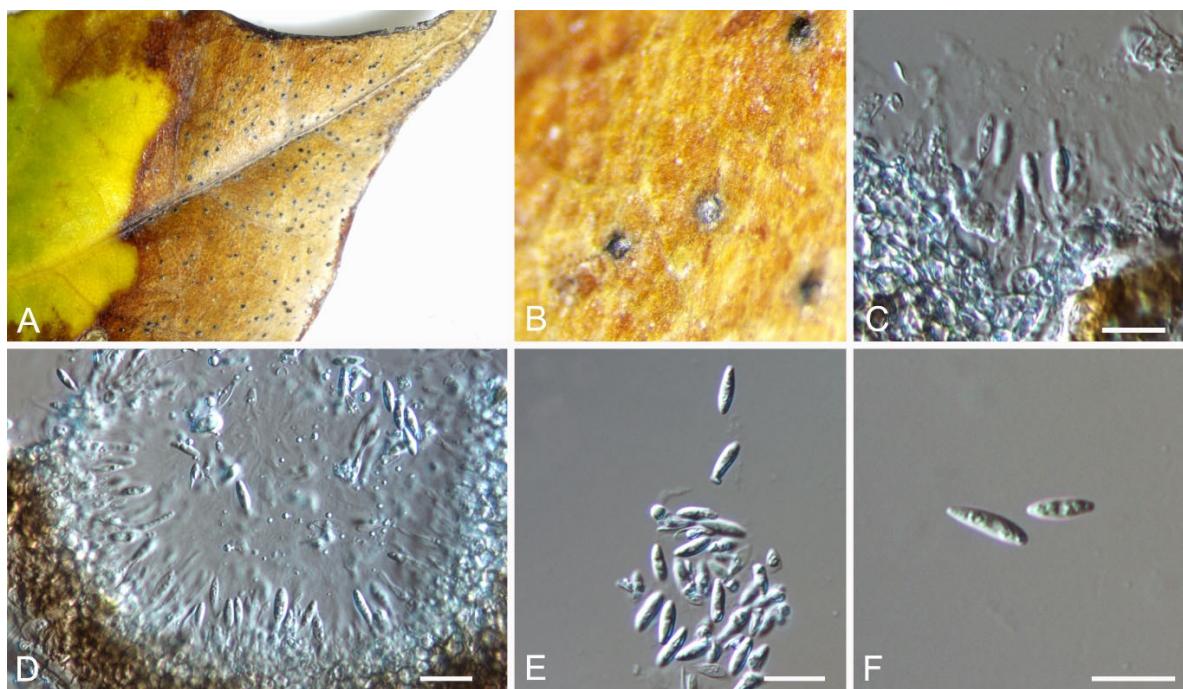

Figure 21. *Diaporthe lithocarpi* (BJFC-S1809). (A,B) Conidiomata on the diseased leaves of *Castanea henryi*; (C) Conidiogenous cells giving rise to conidia; (D) Section through the pycnidium; (E,F) Conidia. Scale bars: C–F = 10 μ m.

3.14. *Gnomoniopsis* Berl.

Gnomoniopsis daii C.M. Tian & N. Jiang, Forests 10(11/1016): 6 (2019) (Figure 22)

Pathogenic on *Castanea mollissima* leaves. Sexual morph: Undetermined. Asexual morph: Conidiomata 30–100 μ m diam., pycnidial, aggregated, globose to pulvinate, black, single ostiolate, forming long and yellow tendrils. Conidiophores reduced to conidiogenous cells. Conidiogenous cells 2.5–18 \times 1.5–3 μ m, cylindrical, hyaline, phialidic, unbranched, straight. Conidia (4.9–)5.1–5.9(–6.2) \times (2.4–)2.5–2.6(–2.7) μ m (\bar{x} = 5.5 \times 2.5 μ m, n = 50), L/W = (1.9–)2–2.2(–2.5) (\bar{x} = 2.2, n = 50), aseptate, hyaline, ellipsoidal, guttulate.

Culture characteristics—Colonies on PDA reaching up to 60 mm in 7 days, flat, velutinous to shortly woolly, dark brown in center, gradually lightening to pale grey at margin; margin diffuse; reverse dark brown to grey.

Material examined—CHINA, Yunnan Province, Zhaotong City, Zhenxiong County, 27°43'28" N, 105°10'35" E, alt. 1280 m, on leaf spots of *Castanea mollissima*, 5 September 2020, N. Jiang (BJFC-S1794, living culture, ZX14-1); Guizhou Province, Zunyi City, Goujiang Town, 27°24'49" N, 106°52'49" E, alt. 1064 m, on leaf spots of *Castanea mollissima*, 7 September 2020, N. Jiang (BJFC-S1795, living culture, CFCC 54345 = ZY11); *ibid.* (living cultures, ZY10-1, ZY10-3, ZY12A).

Notes—The fungus *Gnomoniopsis smithogilvyi* causes fruit rot and branch canker diseases on *Castanea sativa* in Australia and Europe [4,5]. Interestingly, similar symptoms on *Castanea mollissima* in China were caused by two different species. *Gnomoniopsis chinese* causes branch canker, and *G. daii* causes fruit rot [54,55]. In this study, we confirmed the *Gnomoniopsis* pathogen on leaves in China as *G. daii* based on the phylogenetic inference of ITS, *tef1* and *tub2* sequence data (Figure A10), and exactly matched morphology.

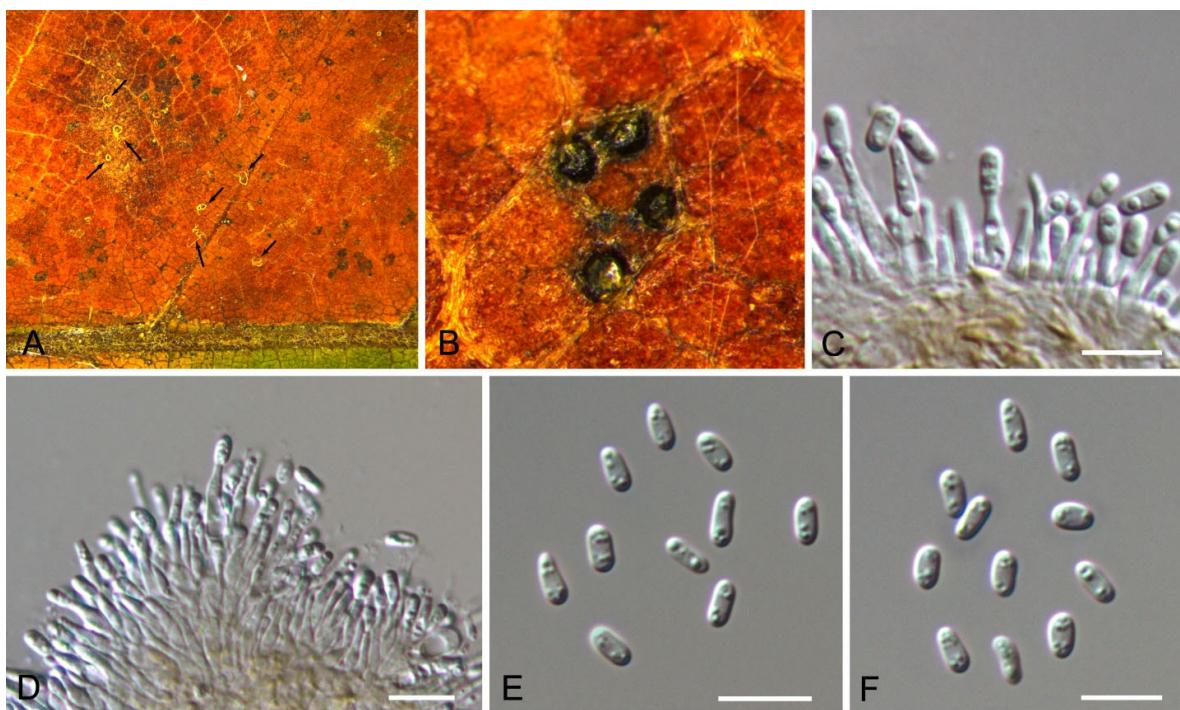

Figure 22. *Gnomoniopsis daii* (BJFC-S1794). (A,B) Conidiomata on the diseased leaves of *Castanea mollissima* (arrows showing orange tendrils); (C,D) Conidiogenous cells giving rise to conidia; (E,F) Conidia. Scale bars: C–F = 10 μ m.

3.15. Pyrisporaceae C.M. Tian & N. Jiang

3.15.1. Pyrisporaceae C.M. Tian & N. Jiang, fam. nov.

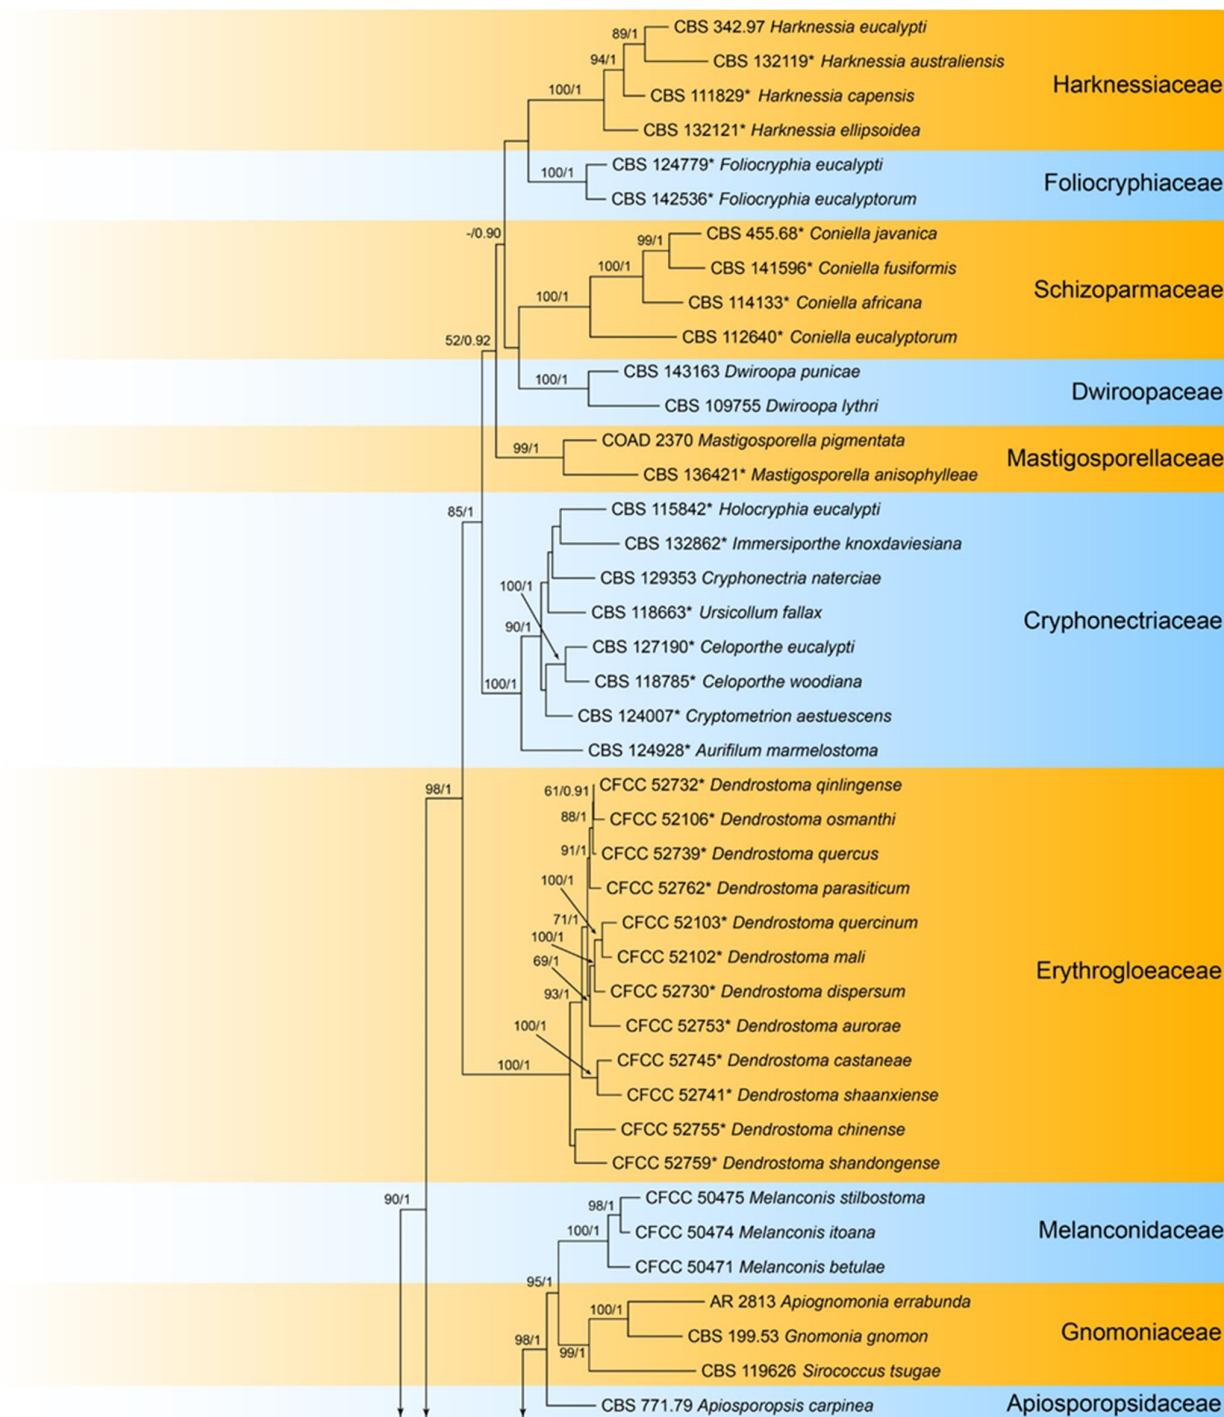

Mycobank: MB 838315

Etymology—named from the type genus, *Pyrispora*.

Type genus—*Pyrispora* C.M. Tian & N. Jiang

Pathogenic or saprobic on *Castanea mollissima* leaves. Sexual morph: Ascomata semi-immersed, aggregated, globose to pulvinate, black, single ostiolate. Ostioles single, dark grey to black. Paraphyses deliquescent. Ascii cylindrical to clavate, 8-spored, bi-seriate, with a distinct apical ring. Ascospores aseptate, hyaline, smooth, fusoid, multiguttulate, straight to slight curved. Asexual morph: Conidiomata pycnidial, aggregated, globose to subglobose, black, single ostiolate. Conidiophores reduced to conidiogenous cells. Conidiogenous cells pyriform base with long neck, hyaline, phialidic, unbranched, straight. Conidia aseptate, hyaline, smooth, ellipsoidal, multiguttulate.

Notes—The fungal order Diaporthales was well-classified based on both morphology and phylogeny in recent years (Figure 23) [56–59]. In this study, the sexual morph was observed on *Castanea* leaves, showing the typical characters of Diaporthales, the ascii with distinct apical ring. Additionally, the asexual morph is distinctive based on the conidiogenous cells with pyriform base and long neck. Hence, we proposed a new family to accommodate this species.

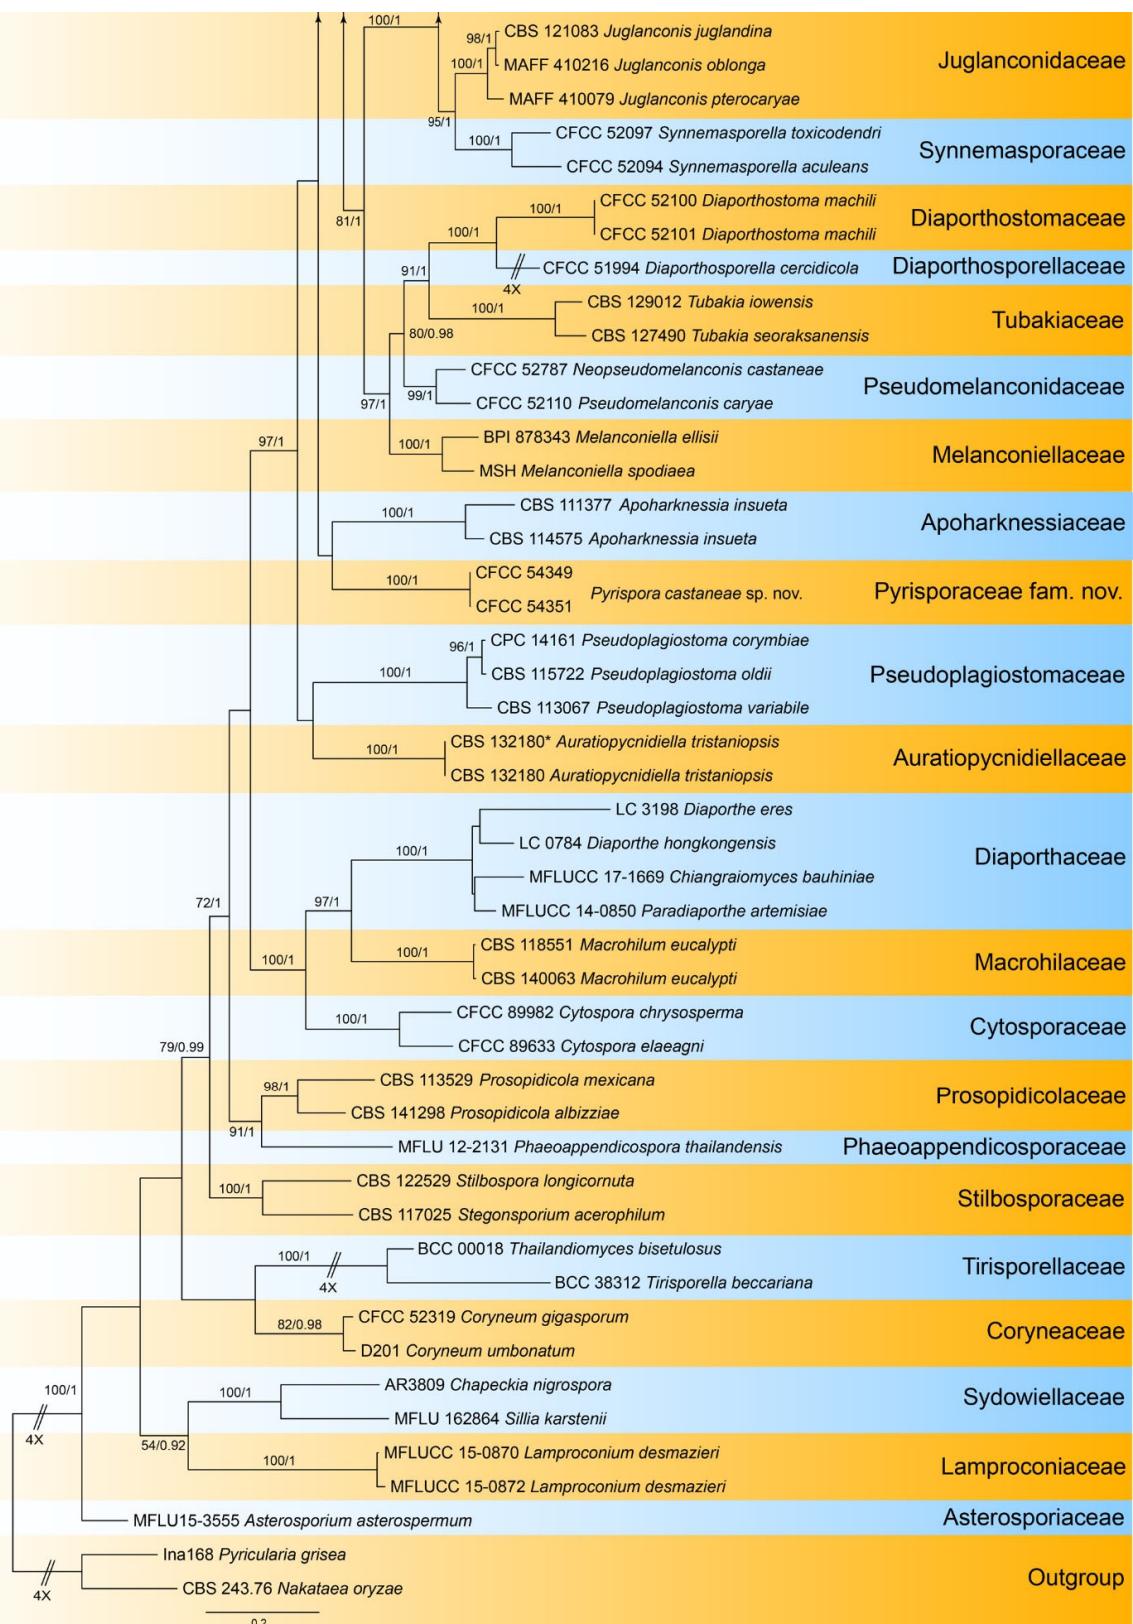

Figure 23. Phylogram generated from RAxML analysis based on combined ITS, LSU, *tef1* and *rpb2* sequence data of Diaporthales isolates. The tree was rooted to *Pyricularia grisea* (Ina 168) and *Nakataea oryzae* (CBS 243.76). The scale bar indicates 0.2 nucleotide changes per site.

3.15.2. *Pyrispora* C.M. Tian & N. Jiang, gen. nov.

Mycobank: MB 838316

Etymology—named for the pyriform base of the conidiogenous cells.

Type species—*Pyrispora castaneae* C.M. Tian & N. Jiang

Pathogenic or saprobic on *Castanea mollissima* leaves. Sexual morph: Ascomata semi-immersed, aggregated, globose to pulvinate, black, single ostiolate. Ostioles single, dark grey to black. Paraphyses deliquescent. Ascii cylindrical to clavate, 8-spored, bi-seriate, with a distinct apical ring. Ascospores aseptate, hyaline, smooth, fusoid, multiguttulate, straight to slight curved. Asexual morph: Conidiomata pycnidial, aggregated, globose to subglobose, black, single ostiolate. Conidiophores reduced to conidiogenous cells. Conidiogenous cells pyriform base with long neck, hyaline, phialidic, unbranched, straight. Conidia aseptate, hyaline, smooth, ellipsoidal, multiguttulate.

3.15.3. *Pyrispora castaneae* C.M. Tian & N. Jiang, sp. nov.

Mycobank: MB 838317

Etymology—named for the host genus, *Castanea*.

Holotype—BJFC-S1798

Pathogenic or saprobic on *Castanea mollissima* leaves. Sexual morph: Ascomata 80–200 µm diam., semi-immersed, aggregated, globose to pulvinate, black, single ostiolate. Ostioles 30–75 µm, diam., single, dark grey to black. Paraphyses deliquescent. Ascii (41–)44.5–52(–58) × (7–)8.5–10.5(–11) µm, cylindrical to clavate, 8-spored, bi-seriate, with a distinct apical ring. Ascospores (11.4–)12.2–14.5(–14.9) × (4.3–)4.4–4.9(–5.2) µm ($\bar{x} = 13.3 \times 4.7$ µm, $n = 50$), L/W = (2.2–)2.5–3(–3.2) ($\bar{x} = 2.9$, $n = 50$), aseptate, hyaline, smooth, fusoid, multiguttulate, straight to slight curved. Asexual morph: Conidiomata 60–250 µm diam., pycnidial, aggregated, globose to subglobose, black, single ostiolate. Conidiophores reduced to conidiogenous cells. Conidiogenous cells 4–7.5 × 2–3.5 µm, pyriform base with long neck, necks up to 45 µm, hyaline, phialidic, unbranched, straight. Conidia (10.4–)11.7–13(–13.9) × (4.1–)4.4–4.9(–5.5) µm ($\bar{x} = 12.3 \times 4.5$ µm, $n = 50$), L/W = (2.2–)2.5–3.2(–3.4) ($\bar{x} = 2.8$, $n = 50$), aseptate, hyaline, smooth, ellipsoidal, multiguttulate (Figures 24 and 25).

Culture characteristics—Colonies on PDA reaching up to 60 mm in 7 days, flat, white, with cottony aerial mycelium and fringed margin; reverse pale yellowish.

Material examined—CHINA, Sichuan Province, Yaan City, Shimian County, 29°13'31" N, 102°21'27" E, alt. 978 m, on leaf spots of *Castanea mollissima*, 10 September 2020, N. Jiang (BJFC-S1798, holotype; ex-type living culture, CFCC 54349 = SM17); *ibid.* (BJFC-S1799, living culture, CFCC 54350 = SM20); *ibid.* (BJFC-S1800, living culture, SM28); *ibid.* (BJFC-S1801, living culture, CFCC 54351 = SM29); *ibid.* (BJFC-S1802, living culture, SM30); *ibid.* (BJFC-S1803, living culture, SM31); Hunan Province, Xiangtan City, 27°48'51" N, 112°71'42" E, alt. 85 m, on leaf spots of *Castanea mollissima*, 9 November 2020, C.M. Tian & N. Jiang (living culture, CFCC 54578 = XT01).

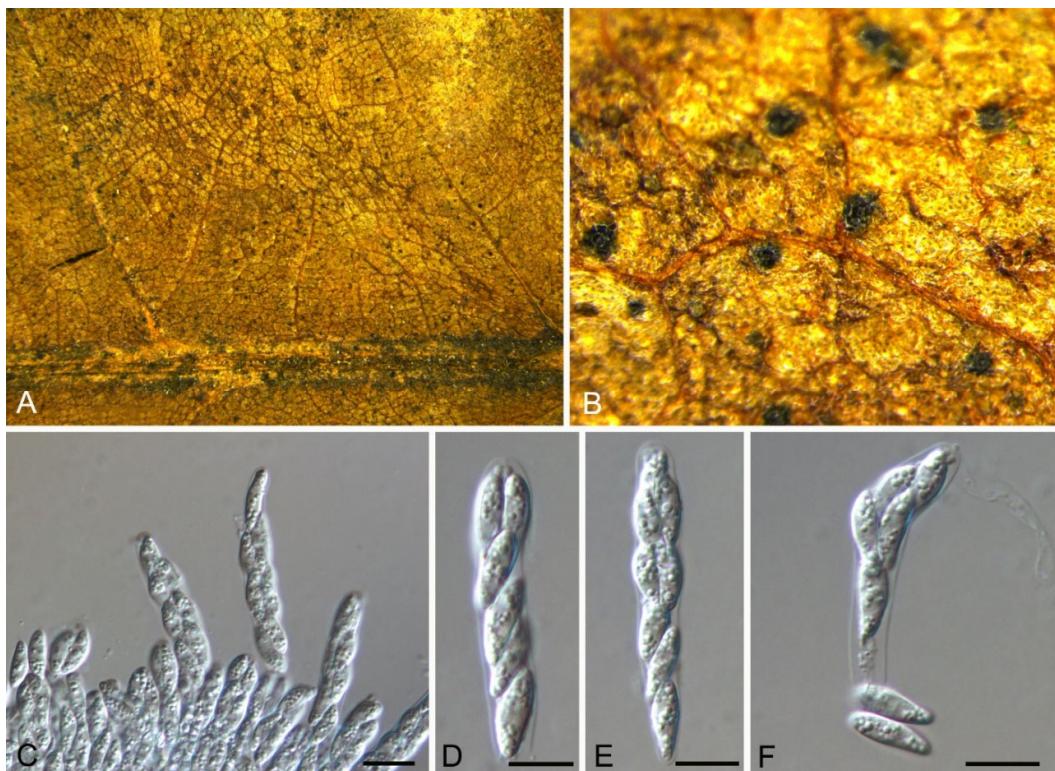

Figure 24. *Pyrispora castaneae* (BJFC-S1800). (A,B) Ascomata on the diseased leaves of *Castanea mollissima*; (C–F) Ascospores. Scale bars: C–F = 10 μ m.

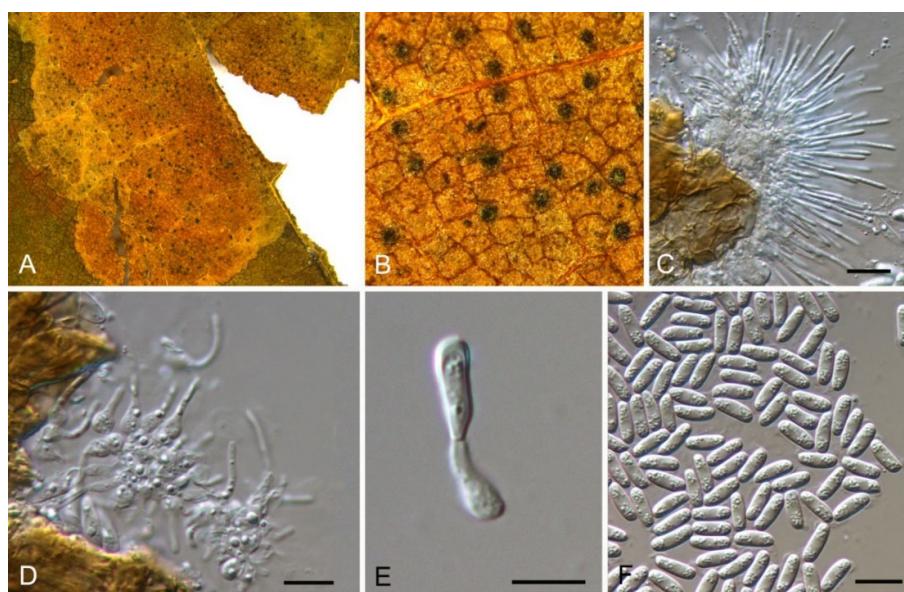

Figure 25. *Pyrispora castaneae* (BJFC-S1798). (A,B) Conidiomata on the diseased leaves of *Castanea mollissima*; (C–E) Conidigenous cells giving rise to conidia; (F) Conidia. Scale bars: C–F = 10 μ m.

3.16. *Coniella Höhn.*

Coniella castaneicola B. Sutton, The Coelomycetes (Kew): 420 (1980) (Figure 26)

Pathogenic on *Castanea mollissima* leaves. Sexual morph: Undetermined. Asexual morph: Conidiomata 100–150 μ m diam., pycnidial, conspicuous, scattered, globose to

subglobose, black, single ostiolate. Conidiophores reduced to conidiogenous cells. Conidiogenous cells $4\text{--}13.5 \times 1.5\text{--}3.5 \mu\text{m}$, simple, hyaline, smooth, tapering. Conidia $(16.7\text{--})18.4\text{--}21.3(22.3) \times (2.7\text{--})2.8\text{--}3.2(3.3) \mu\text{m}$ ($\bar{x} = 19.9 \times 3 \mu\text{m}$, $n = 50$), L/W = $(5.1\text{--})6\text{--}7.2(7.3)$ ($\bar{x} = 6.6$, $n = 50$), aseptate, initially hyaline, becoming pale brown, smooth, cylindrical, linear, apex acute to nearly rounded, base truncate, smooth-walled, multiguttulate, enclosed in a persistent mucoid sheath.

Culture characteristics—Colonies on PDA reaching up to 60 mm in 10 days, flat, white, aerial mycelium spreads in irregular concentric zones. Conidiomata were formed after 15 days.

Material examined—CHINA, Guizhou Province, Zunyi City, Goujiang Town, $27^{\circ}24'49''$ N, $106^{\circ}52'49''$ E, alt. 1064 m, on leaf spots of *Castanea mollissima*, 7 September 2020, N. Jiang (BJFC-S1793, living culture, CFCC 54344 = ZY7-1); *ibid.* (living culture, ZY7-2).

Notes—The genus *Coniella* was well classified recently [60]. However, *Coniella castaneicola* was not studied for lacking of fresh collections and DNA data. In present study, we obtained fresh *Coniella* isolates from *Castanea mollissima*, and found it distinct from others in the phylogram (Figure A11). However, specimen in present study shared similar conidial morphology with the original description of *Coniella castaneicola* ($20 \times 2\text{--}2.5 \mu\text{m}$) [61], hence we temporarily assign it to *C. castaneicola*.

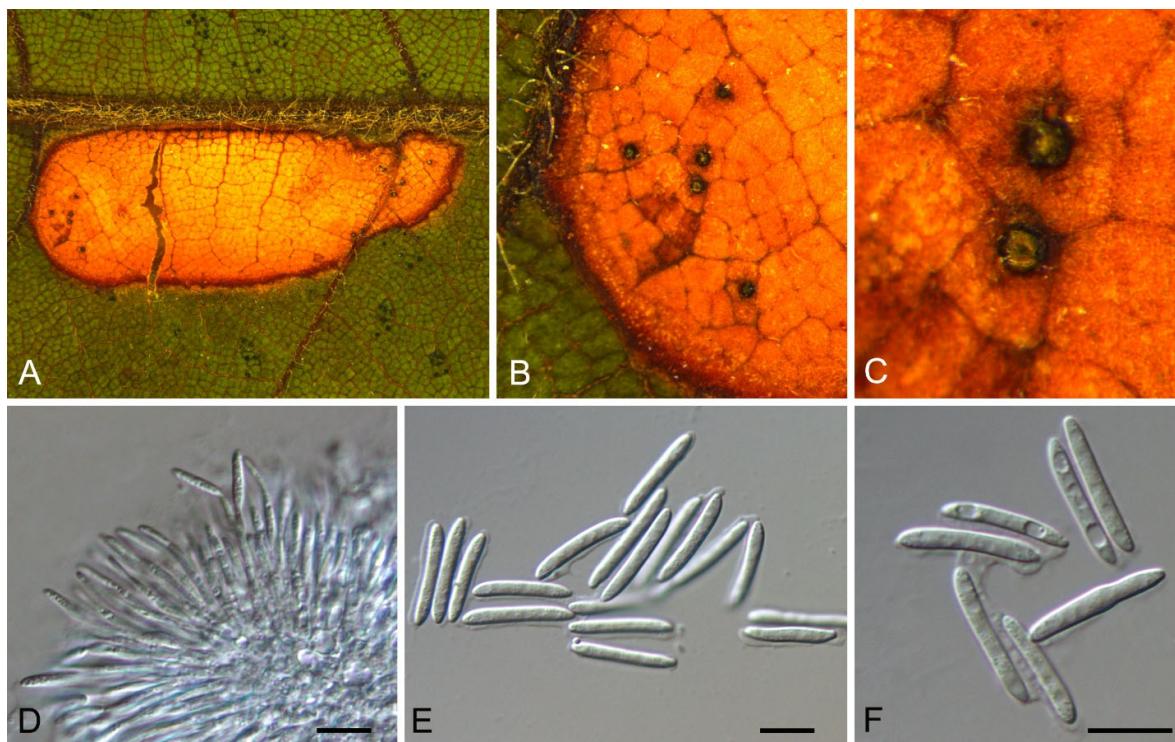

Figure 26. *Coniella castaneicola* (BJFC-S1793). (A–C) Conidiomata on the diseased leaves of *Castanea mollissima*; (D) Conidiogenous cells giving rise to conidia; (E,F) Conidia. Scale bars: D–F = $10 \mu\text{m}$.

3.17. *Tubakia* B. Sutton

Tubakia dryinoides C. Nakash., Fungal Systematics and Evolution 1: 80 (2018) (Figure 27)

Pathogenic or saprobic on *Castanea mollissima* leaves. Sexual morph: Undetermined. Asexual morph: Conidiomata $70\text{--}120 \mu\text{m}$ diam., pycnothyrial, conspicuous, aggregated, superficial, circular or subcircular, black. Conidiophores reduced to conidiogenous cells, arising from the underside of the scutella, around the columella, radiating. Conidiogenous cells $5\text{--}14 \times 2.5\text{--}5 \mu\text{m}$, cylindrical, conical, hyaline to brown, thin-walled, smooth, apex

obtuse to truncate. Conidia $(10.4\text{--}11.5\text{--}15.6\text{--}17.7) \times (5.1\text{--}5.3\text{--}6.1\text{--}6.5) \mu\text{m}$ ($\bar{x} = 13.6 \times 5.7 \mu\text{m}$, $n = 50$), $L/W = (1.7\text{--}1.9\text{--}2.9\text{--}3.4)$ ($\bar{x} = 2.4$, $n = 50$), aseptate, hyaline to pale brown, smooth, cylindrical to obovoid.

Culture characteristics—Colonies on PDA reaching up to 60 mm in 14 days, flat, creamy white, aerial mycelium forming concentric rings. Conidiomata were formed after 15 days.

Material examined—CHINA, Sichuan Province, Yaan City, Shimian County, $29^{\circ}13'31''\text{N}$, $102^{\circ}21'27''\text{E}$, alt. 978 m, on leaf spots of *Castanea mollissima*, 10 September 2020, N. Jiang (BJFC-S1796; living culture, CFCC 54346 = SM10-1); *ibid.* (living culture, = SM10).

Notes—*Tubakia dryinoides* was described from *Castanea crenata* and *Quercus phillyraeoides* in Japan [62]. In present study, strains from diseased chestnut leaves formed a supported clade with the ex-type strain NBRC 9267 (Figure A12), and shared similar morphology. Hence, we identified our strains as *T. dryinoides*, which represented a new host and geographical record.

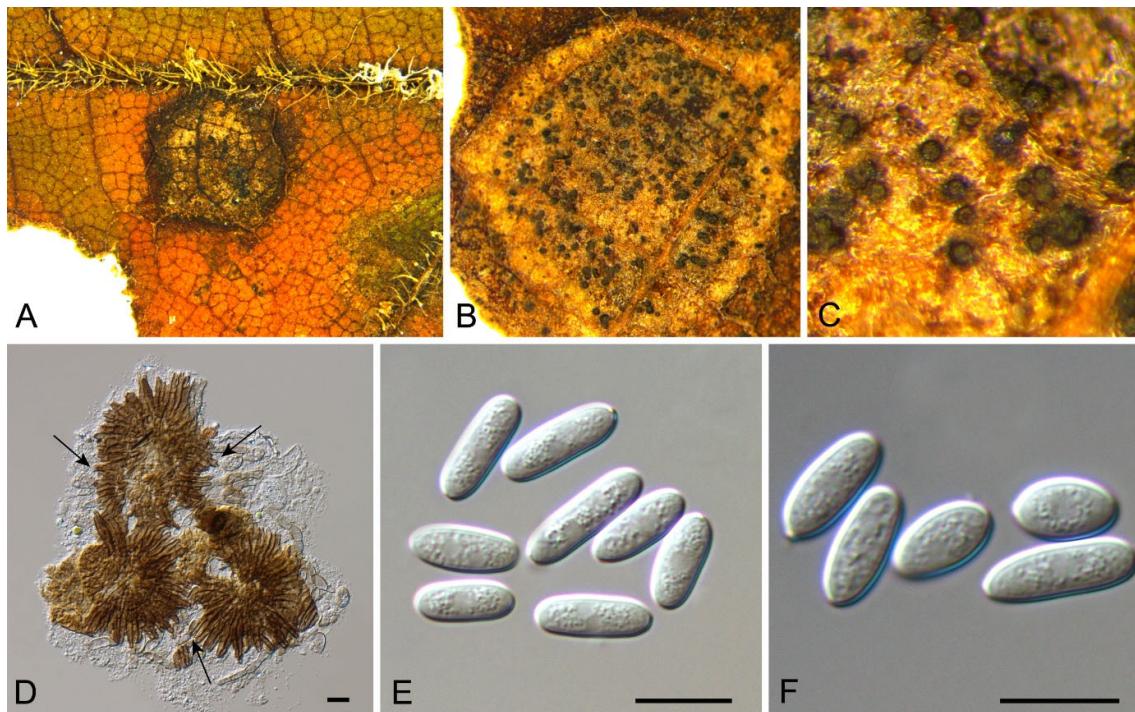

Figure 27. *Tubakia dryinoides* (BJFC-S1796). (A–C) Pycnothryia on the diseased leaves of *Castanea mollissima*; (D) Conidiogenous cells giving rise to conidia; (E,F) Conidia. Scale bars: D–F = 10 μm .

3.18. *Colletotrichum* Corda

3.18.1. *Colletotrichum fructicola*

Colletotrichum fructicola Prihast., L. Cai & K.D. Hyde, Fungal Divers. 39: 96 (2009)

Pathogenic on *Castanea henryi* and *C. mollissima* leaves. Sexual morph: Undetermined.

Asexual morph was observed on PDA: Conidiomata, acervular, aggregated, orange. Conidiophores hyaline, septate, branched. Conidiogenous cells $5\text{--}17.5 \times 1.5\text{--}3 \mu\text{m}$, hyaline, cylindrical to ampulliform. Conidia $(10.8\text{--}11.2\text{--}16.9\text{--}17.9) \times (3.1\text{--}3.2\text{--}5.4\text{--}5.9) \mu\text{m}$ ($\bar{x} = 14.7 \times 4.3 \mu\text{m}$, $n = 50$), $L/W = (3.1\text{--}3.2\text{--}3.5\text{--}3.6)$ ($\bar{x} = 3.4$, $n = 50$), aseptate, hyaline, smooth, cylindrical, both ends rounded.

Culture characteristics—Colonies on PDA reaching up to 60 mm in 5 days, flat with entire edge, aerial mycelium dense, cottony, grey to dark grey in the centre, white at the margin; reverse greyish green.

Material examined—CHINA, Sichuan Province, Yaan City, Shimian County, 29°13'31" N, 102°21'27" E, alt. 978 m, on leaf spots of *Castanea mollissima*, 10 September 2020, N. Jiang (living cultures, SM6, SM9, SM13, SM14, SM16, SM30, SM31); Hunan Province, Shaoshan City, Yintian Town, 27°52'04" N, 112°35'03" E, alt. 73 m, on leaf spots of *Castanea mollissima*, 9 November 2020, C.M. Tian & N. Jiang (living cultures, SS01, SS14); Hunan Province, Xiangtan City, 27°48'51" N, 112°71'42" E, alt. 85 m, on leaf spots of *Castanea mollissima*, 9 November 2020, N. Jiang (living cultures, XT08, XT12, XT14-2, XT15); Hunan Province, Changsha City, Changsha County, Jinjing Town, 28°58'52" N, 113°34'38" E, alt. 63 m, on leaf spots of *Castanea henryi*, 10 November 2020, C.M. Tian & N. Jiang (living culture, JJ21).

Notes—*Colletotrichum fructicola* was described from *Coffea arabica* in Thailand [63], and subsequently found to infect several economic plants in China, such as *Camellia sinensis*, *Citrus sinensis*, *Morus alba*, *Pyrus pyrifolia* and *Vitis vinifera* [64]. In present study, strains from diseased chestnut leaves formed a supported clade with *Colletotrichum fructicola* (Figure A13), and shared similar morphology. Hence, we identified our strains as *C. fructicola*, and *Castanea henryi* and *C. mollissima* represented two new host records.

3.18.2. *Colletotrichum henanense*

Colletotrichum henanense F. Liu & L. Cai, Persoonia 35: 80 (2015)

Pathogenic on *Castanea mollissima* leaves. Sexual morph: Undetermined. Asexual morph was observed on PDA: Conidiomata, acervular, aggregated, orange. Conidio-phores hyaline, septate, branched. Conidiogenous cells 4.5–15 × 1.5–2.5 µm, hyaline, cylindrical to ampulliform. Conidia (8.8–)11.5–13.2(–17.2) × (3–)3.4–5.1(–5.8) µm ($\bar{x} = 12.2 \times 4.3$ µm, $n = 50$), L/W = (2.5–)2.6–2.9(–3) ($\bar{x} = 2.7$, $n = 50$), aseptate, hyaline, smooth, cylindrical, both ends rounded.

Culture characteristics—Colonies on PDA reaching up to 60 mm in 5 days, flat with entire edge, aerial mycelium dense, cottony, grey to dark grey in the centre, white at the margin; reverse greyish green.

Material examined—CHINA, Sichuan Province, Yaan City, Shimian County, 29°13'31" N, 102°21'27" E, alt. 978 m, on leaf spots of *Castanea mollissima*, 10 September 2020, N. Jiang (living cultures, SM12, SM22, SM33); Hunan Province, Shaoshan City, Yintian Town, 27°52'04" N, 112°35'03" E, alt. 73 m, on leaf spots of *Castanea mollissima*, 9 November 2020, C.M. Tian & N. Jiang (living cultures, SS02, SS04); Yunnan Province, Zhaotong City, Zhenxiong County, 27°43'28" N, 105°10'35" E, alt. 1280 m, on leaf spots of *Castanea mollissima*, 5 September 2020, N. Jiang (living culture, ZX2-1); Hunan Province, Changsha City, Changsha County, Kaihui Town, 28°58'12" N, 113°25'48" E, alt. 65 m, on leaf spots of *Castanea mollissima*, 10 November 2020, C.M. Tian & N. Jiang (living culture, KH1).

Notes—*Colletotrichum henanense* was initially proposed as the leaf pathogen of *Camellia sinensis* and *Cirsium japonicum* in China [65]. Later, it was recorded to cause anthracnose of *Camellia oleifera* in China [66]. In the present study, strains from diseased chestnut leaves formed a supported clade with *Colletotrichum henanense* (Figure A13), and shared similar morphology. Hence, we identified our strains as *C. henanense*, and *Castanea mollissima* represented a new host record.

3.18.3. *Colletotrichum jiangxiense*

Colletotrichum jiangxiense F. Liu & L. Cai, Persoonia 35: 82 (2015)

Pathogenic on *Castanea mollissima* leaves. Sexual morph: Undetermined. Asexual morph: Undetermined.

Culture characteristics—Colonies on PDA reaching up to 60 mm in 7 days, flat with entire edge, aerial mycelium dense, cottony, white to grey; reverse olivaceous.

Material examined—CHINA, Sichuan Province, Yaan City, Shimian County, 29°13'31" N, 102°21'27" E, alt. 978 m, on leaf spots of *Castanea mollissima*, 10 September 2020, N. Jiang (living culture, SM21); Yunnan Province, Zhaotong City, Zhenxiong

County, 27°43'28" N, 105°10'35" E, alt. 1280 m, on leaf spots of *Castanea mollissima*, 5 September 2020, N. Jiang (living culture, ZX10-1); Guizhou Province, Zunyi City, Goujiang Town, 27°24'49" N, 106°52'49" E, alt. 1064 m, on leaf spots of *Castanea mollissima*, 7 September 2020, N. Jiang (living cultures, ZY12, ZY12B).

Notes—*Colletotrichum jiangxiense* was previously described from *Camellia sinensis* in China [65], and subsequently discovered from *Citrus sinensis* [67]. In present study, strains from diseased chestnut leaves formed a supported clade with *Colletotrichum jiangxiense* (Figure A13). Hence, we identified our strains as *C. jiangxiense*, and *Castanea mollissima* represented a new host record.

3.18.4. *Colletotrichum karsti* You L. Yang, Zuo Y. Liu, K.D. Hyde & L. Cai, Cryptog. Mycol. 32(3): 241 (2011)

Pathogenic on *Castanea mollissima* leaves. Sexual morph: Undetermined. Asexual morph: Undetermined.

Culture characteristics—Colonies on PDA reaching up to 60 mm in 6 days, flat with entire margin, aerial mycelium dense, cottony, initially white, becoming grey with age; reverse pale brown.

Material examined—CHINA, Guizhou Province, Zunyi City, Goujiang Town, 27°24'49" N, 106°52'49" E, alt. 1064 m, on leaf spots of *Castanea mollissima*, 7 September 2020, N. Jiang (living cultures, CFCC 54365 = ZY3B, ZY3B-1).

Notes—*Colletotrichum karsti* was described from *Arundina graminifolia*, *Calanthe argenteostriata*, *Eria coronaria*, *Pleione bulbocodioides* and *Vanda* sp. in China [68]. In the present study, strains from diseased chestnut leaves formed a supported clade with *Colletotrichum karsti* (Figure A14). Hence, we identified our strains as *C. karsti*, and *Castanea mollissima* represented a new host record.

3.18.5. *Colletotrichum nymphaeae* (Pass.) Aa, Netherlands Journal of Plant Pathology, Supplement 1 84(3): 110 (1978)

Pathogenic on *Castanea mollissima* leaves. Sexual morph: Undetermined. Asexual morph: Undetermined.

Culture characteristics—Colonies on PDA reaching up to 60 mm in 8 days, flat with entire edge, aerial mycelium dense, cottony, white to grey; reverse olivaceous.

Material examined—CHINA, Sichuan Province, Yaan City, Shimian County, 29°13'31" N, 102°21'27" E, alt. 978 m, on leaf spots of *Castanea mollissima*, 10 September 2020, N. Jiang (living cultures, CFCC 54366 = SM26, SM26-1).

Notes—*Colletotrichum nymphaeae* was recorded to be associated with several hosts, including *Camellia oleifera*, *Citrus aurantifolia*, *Juglans regia*, *Malus domestica*, *Prunus salicina* and *Vitis vinifera* [69]. In the present study, strains from diseased chestnut leaves formed a supported clade with *Colletotrichum nymphaeae* (Figure A15). Hence, we identified our strains as *C. nymphaeae*, and *Castanea mollissima* represented a new host record.

4. Discussion

Castanea henryi and *C. mollissima* are two crops currently cultivated in plantations of China, and suffering from cankers, leaf spots and fruit rot diseases commonly. During our investigations in the past years, *Cryphonectria parasitica* and *Dendrostoma* spp. were commonly occurring in most plantations, causing mild to serious cankers depending on the management [2,10]. *Gnomoniopsis chinensis* caused fatal stem and branch canker disease in only Hebei Province [60]. Compared to the cankers, leaf spots are usually neglected. In present study, we focused on the leaf-inhabiting fungi, identified them to 26 fungal species using phenotypic characters and the multi-locus phylogeny.

From Table 3, most fungi (92.3%) belong to Sordariomycetes and the rest two species belong to Dothideomycetes. This result is nearly congruent as we expected, because Sordariomycetes is a species-rich class and contains many plant pathogens [69]. Within Sordariomycetes, Amphisphaerales (45.8%), Botryosphaerales (12.5%), Diaporthales (33.3%) and Glomerellales (20.8%) are identified. They contain famous plant pathogens such as

pestalotioid taxa, Botryosphaeria-like taxa, diaporthalean fungi and *Colletotrichum* species. These fungi were documented in the monograph of chestnut disease by Xie in 1998 [44]. However, genus and species concepts have changed a lot in recent years. For example, the old name *Colletotrichum gloeosporioides* has been expanded to a group of species named *Colletotrichum gloeosporioides* species complex [70], hence the chestnut-inhabiting *Colletotrichum* needs to be re-identified to particular one or several species. The genus *Pestalotiopsis* s. l. was separated into three genera, namely *Pestalotiopsis* s. s., *Neopestalotiopsis* and *Pseudopestalotiopsis* based on phylogeny [50]. In addition, species with similar morphology from the same host, especially resulting into same symptoms, are not easy to be distinguished without molecular approach in previous studies. *Gnomoniopsis daii* from Chinese chestnut and *Gnomoniopsis smithogilvyi* (*G. castaneae*) from European chestnut were likely identified to *Phomopsis* (now *Diaporthe*) species for extremely similar morphology.

According to the filed investigation and sample observation, *Colletotrichum* spp., *Neopestalotiopsis* spp., *Pestalotiopsis kenyana* and *Phyllosticta capitalensis* are now common pathogens in plantations of *Castanea henryi* and *C. mollissima*. Pathogenicity tests and disease control methods are required to be conducted in the future.

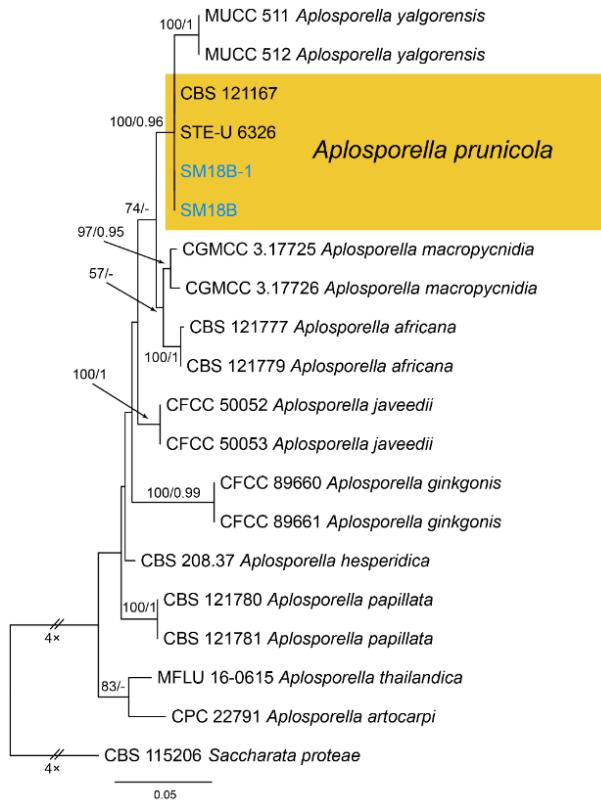

Figure A1. Phylogram generated from RAXML analysis based on combined ITS and *tef1* sequence data of *Aplosporella* isolates. The tree was rooted to *Saccharata proteae* (CBS 115206). The scale bar indicates 0.05 nucleotide changes per site. Isolates from this study are marked in blue, and the identified species is marked in yellow.

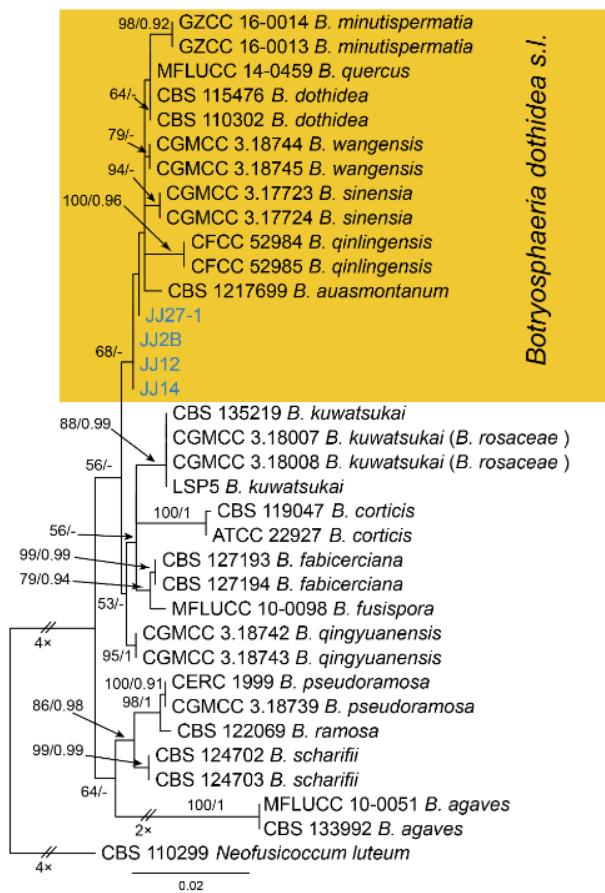

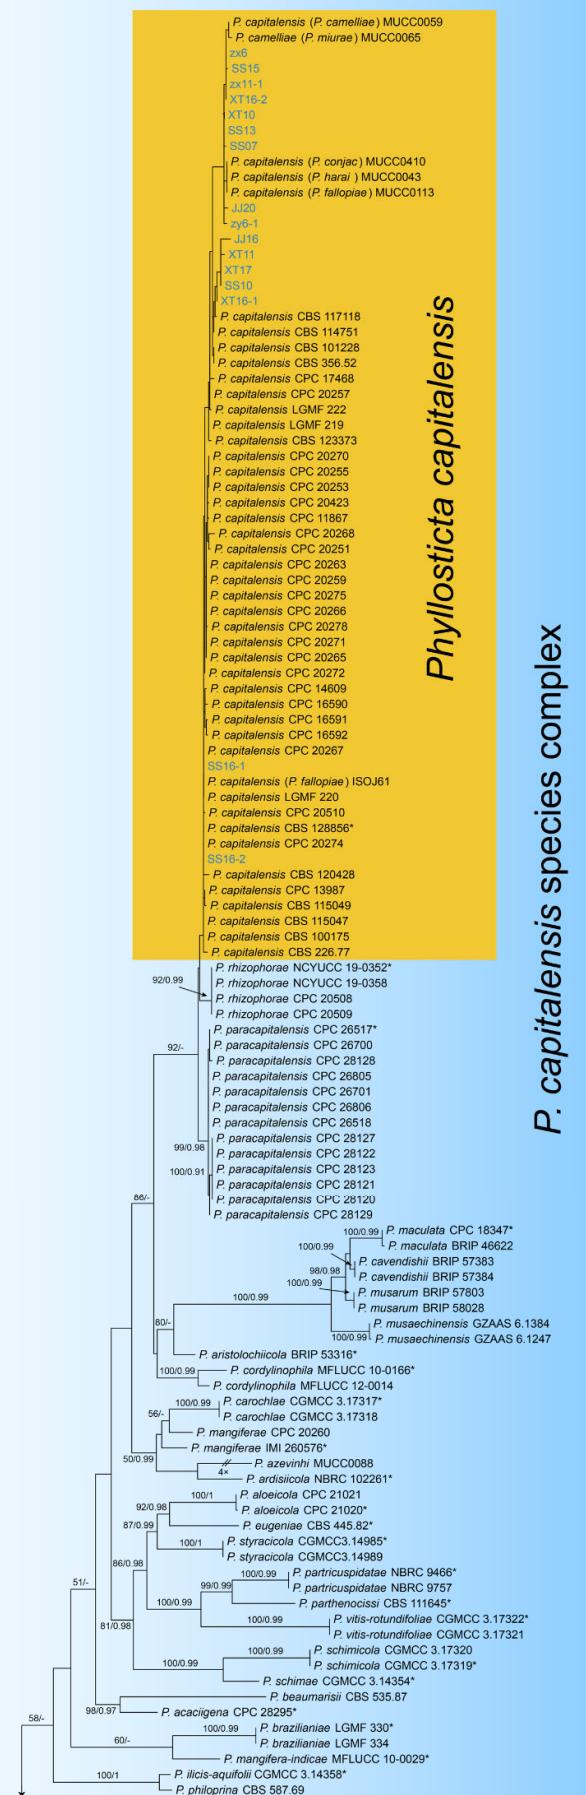

Figure A2. Phylogram generated from RAxML analysis based on combined ITS, *tef1* and *tub2* sequence data of *Botryosphaeria* isolates. The tree was rooted to *Neofusicoccum luteum* (CBS 110229). The scale bar indicates 0.02 nucleotide changes per site. Isolates from this study are marked in blue, and the identified species is marked in yellow.

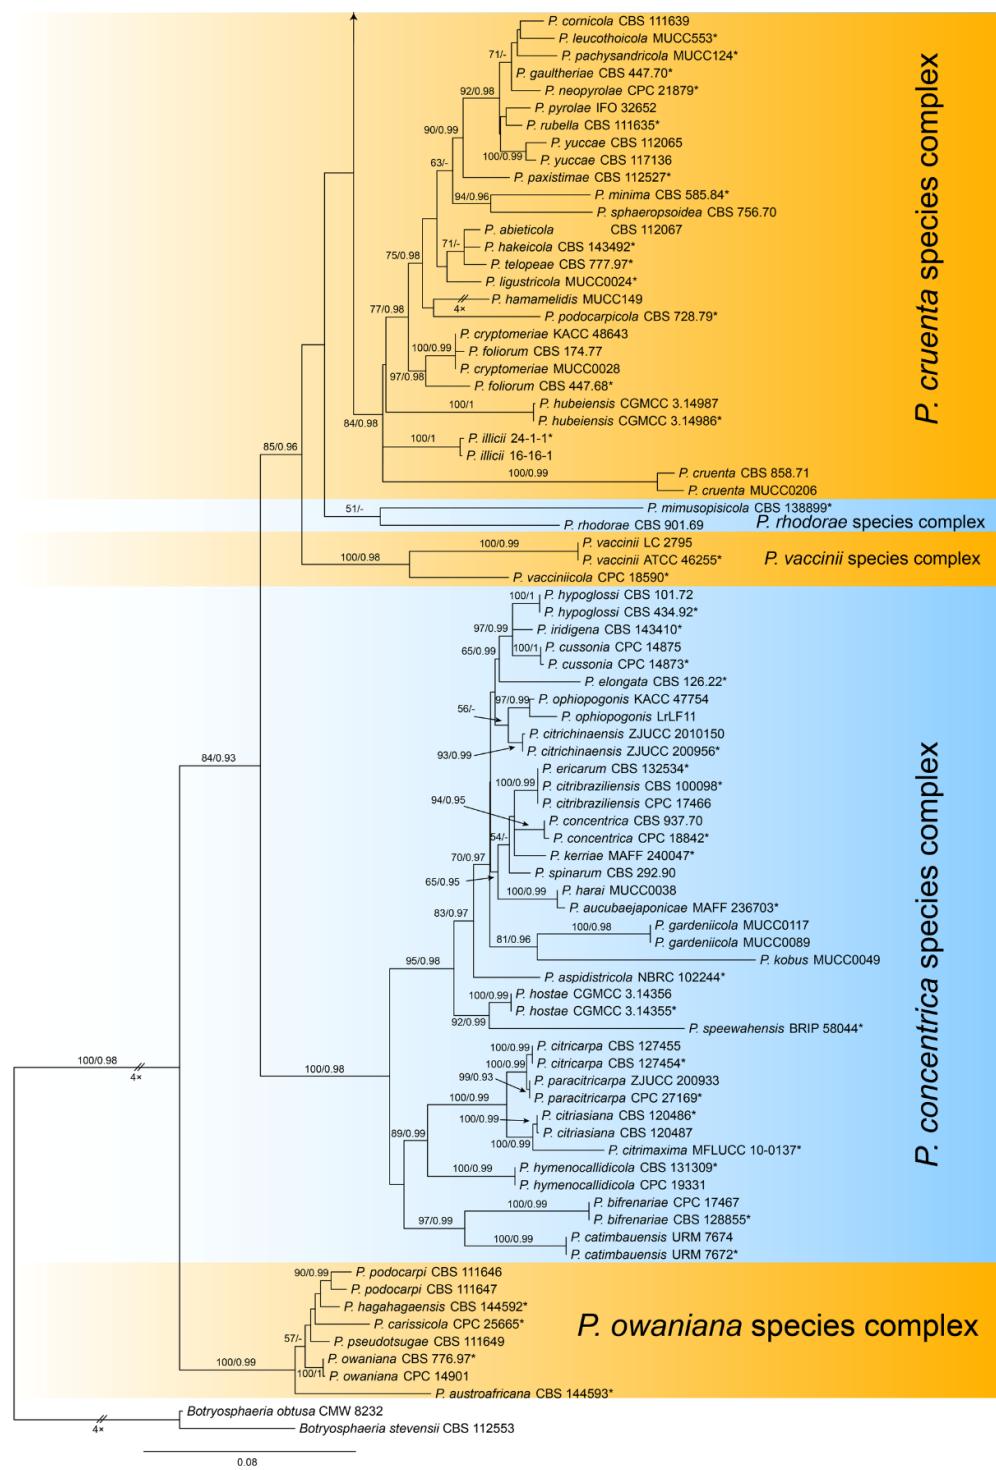

Figure A3. Phylogram generated from RAxML analysis based on combined ITS, LSU, *act*, *gapdh* and *tef1* sequence data of *Phyllosticta* isolates. The tree was rooted to *Botryosphaeria obtusa* (CMW 8232) and *B. stevensii* (CBS 112553). The scale bar indicates 0.08 nucleotide changes per site. Isolates from this study are highlighted, and ex-type strains are marked with *.

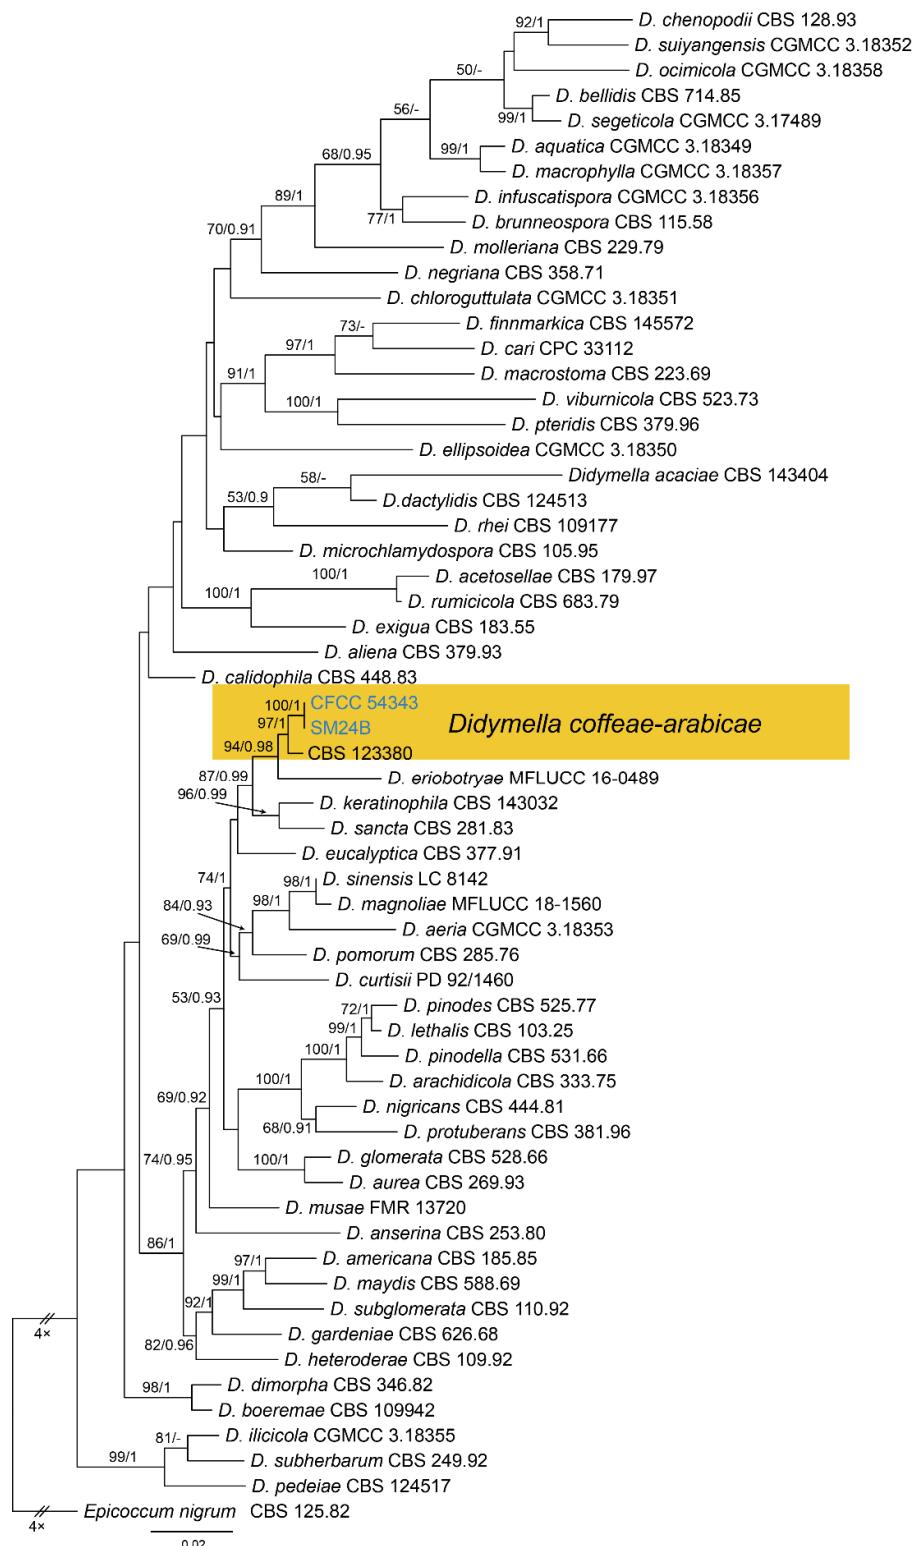

Figure A4. Phylogram generated from RAxML analysis based on combined ITS, LSU, *rpb2* and *tub2* sequence data of *Didymella* isolates. The tree was rooted to *Epicoccum nigrum* (CBS 125.82). The scale bar indicates 0.02 nucleotide changes per site. Isolates from this study are marked in blue, and the identified species is marked in yellow.

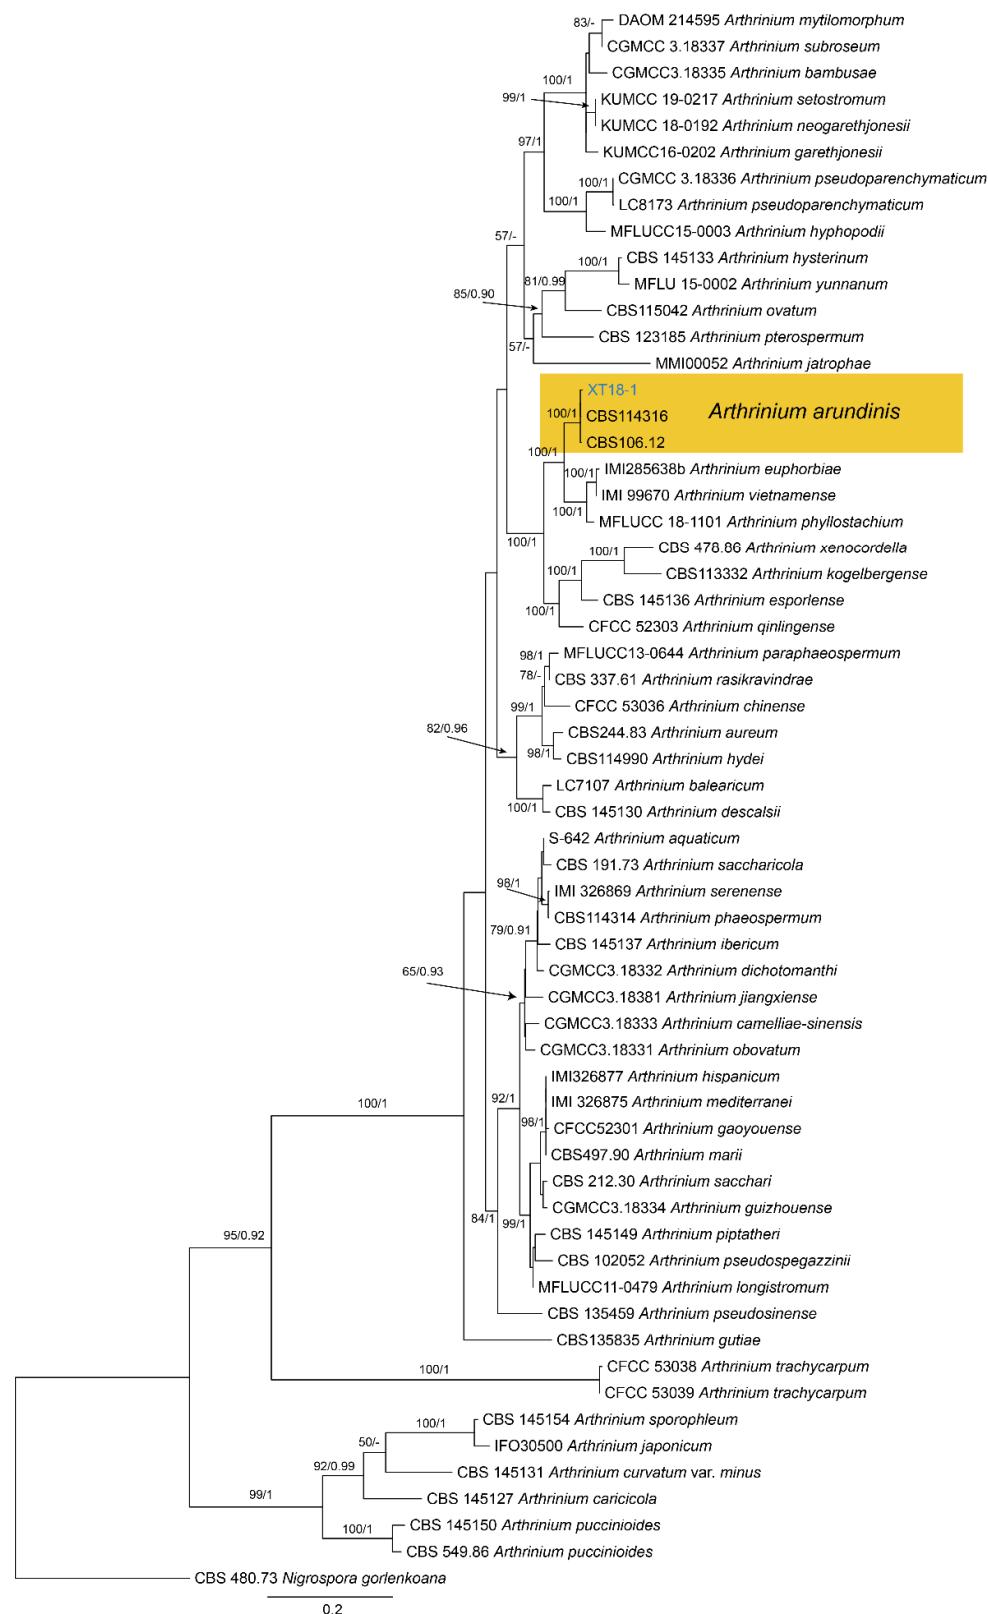

Figure A5. Phylogram generated from RAxML analysis based on combined ITS, *tef1* and *tub2* sequence data of *Arthrinium* isolates. The tree was rooted to *Nigrospora gorlenkoana* (CBS 480.73). The scale bar indicates 0.2 nucleotide changes per site. Isolates from this study are marked in blue, and the identified species is marked in yellow.

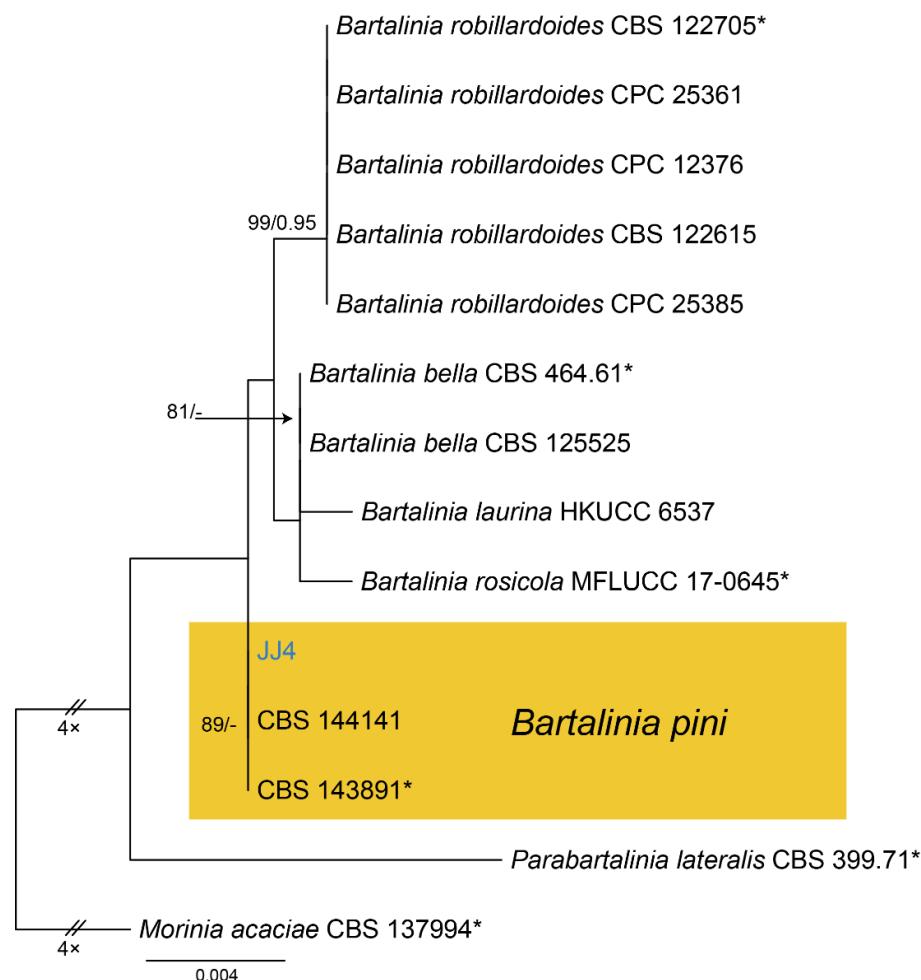

Figure A6. Phylogram generated from RAxML analysis based on combined ITS and LSU sequence data of *Bartalinia* isolates. Table 137994. The scale bar indicates 0.004 nucleotide changes per site. Isolate from this study is marked in blue, ex-type strains are marked with *, and the identified species is marked in yellow.

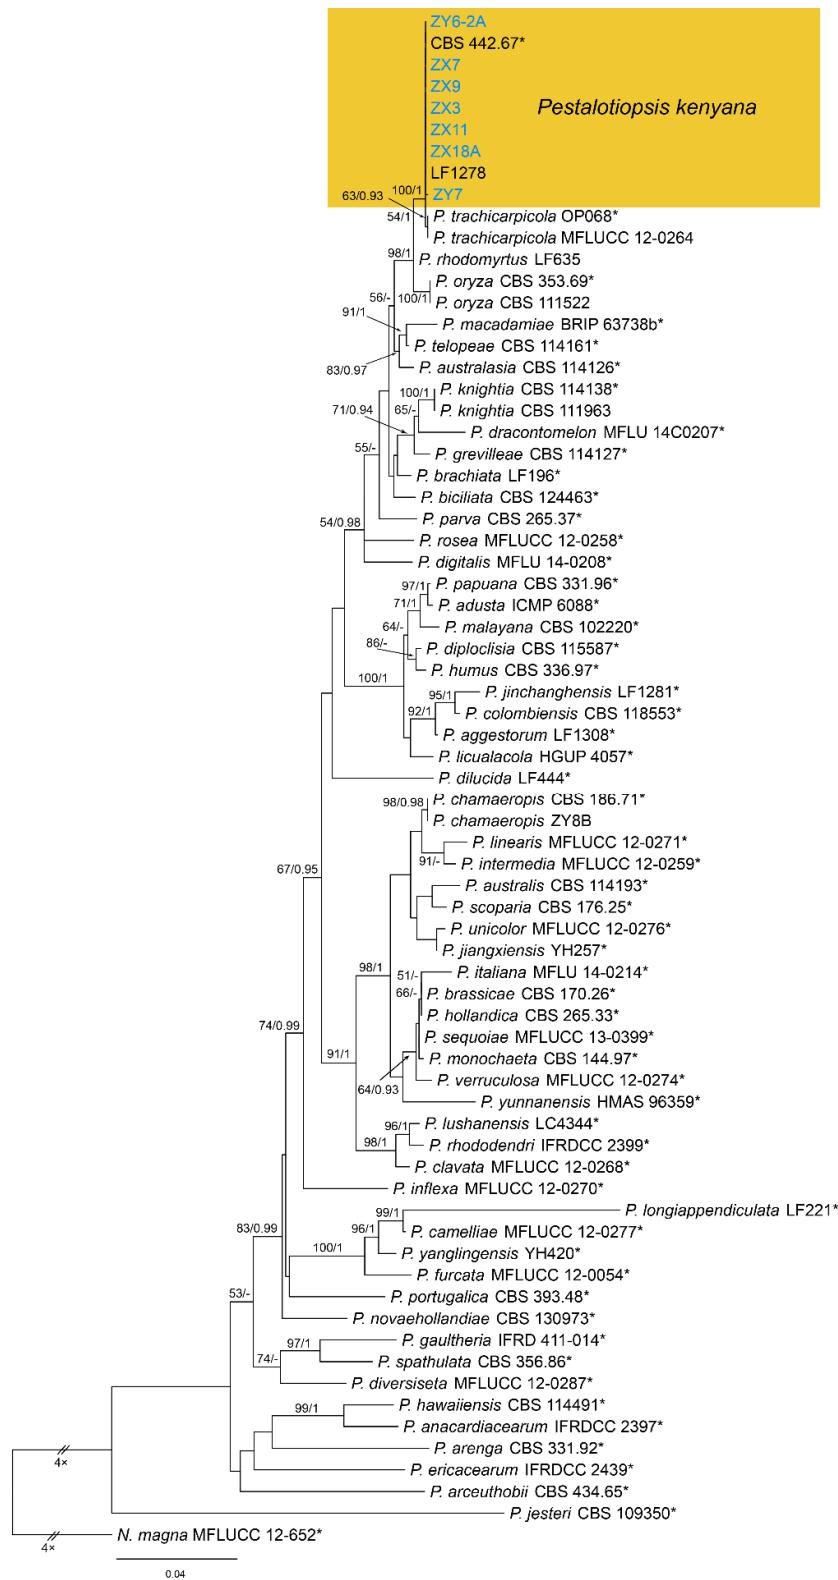

Figure A7. Phylogram generated from RAxML analysis based on combined ITS, *tef1* and *tub2* sequence data of *Pestalotiopsis* isolates. The tree was rooted to *Neopestalotiopsis magna* (MFLUCC 12-652). The scale bar indicates 0.04 nucleotide changes per site. Isolates from this study are marked in blue, ex-type strains are marked with *, and the identified species is marked in yellow.

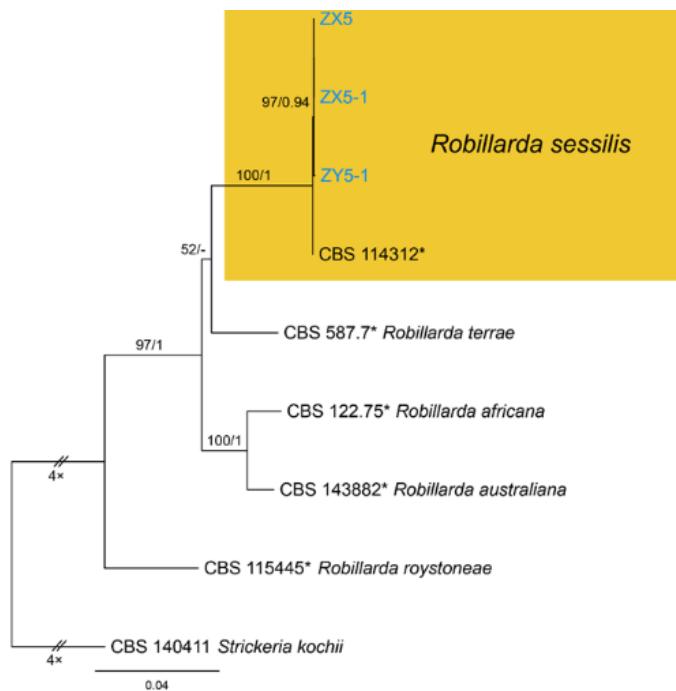

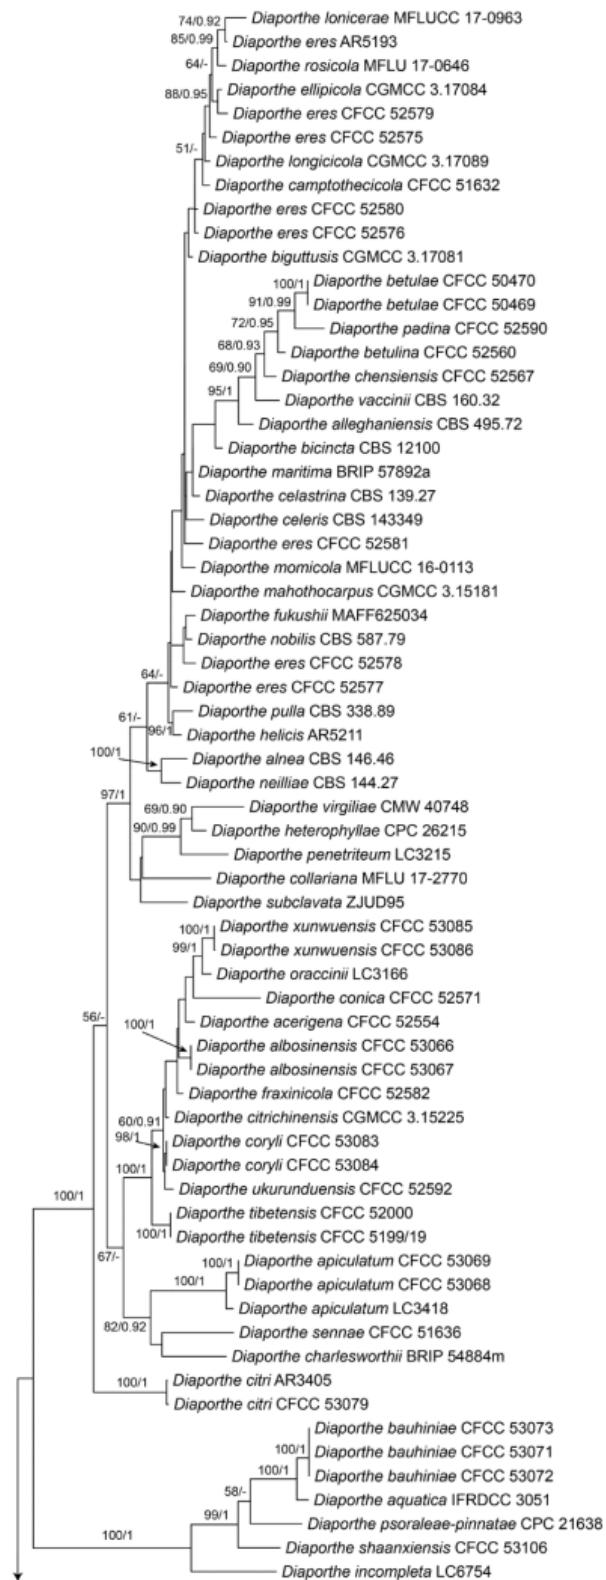

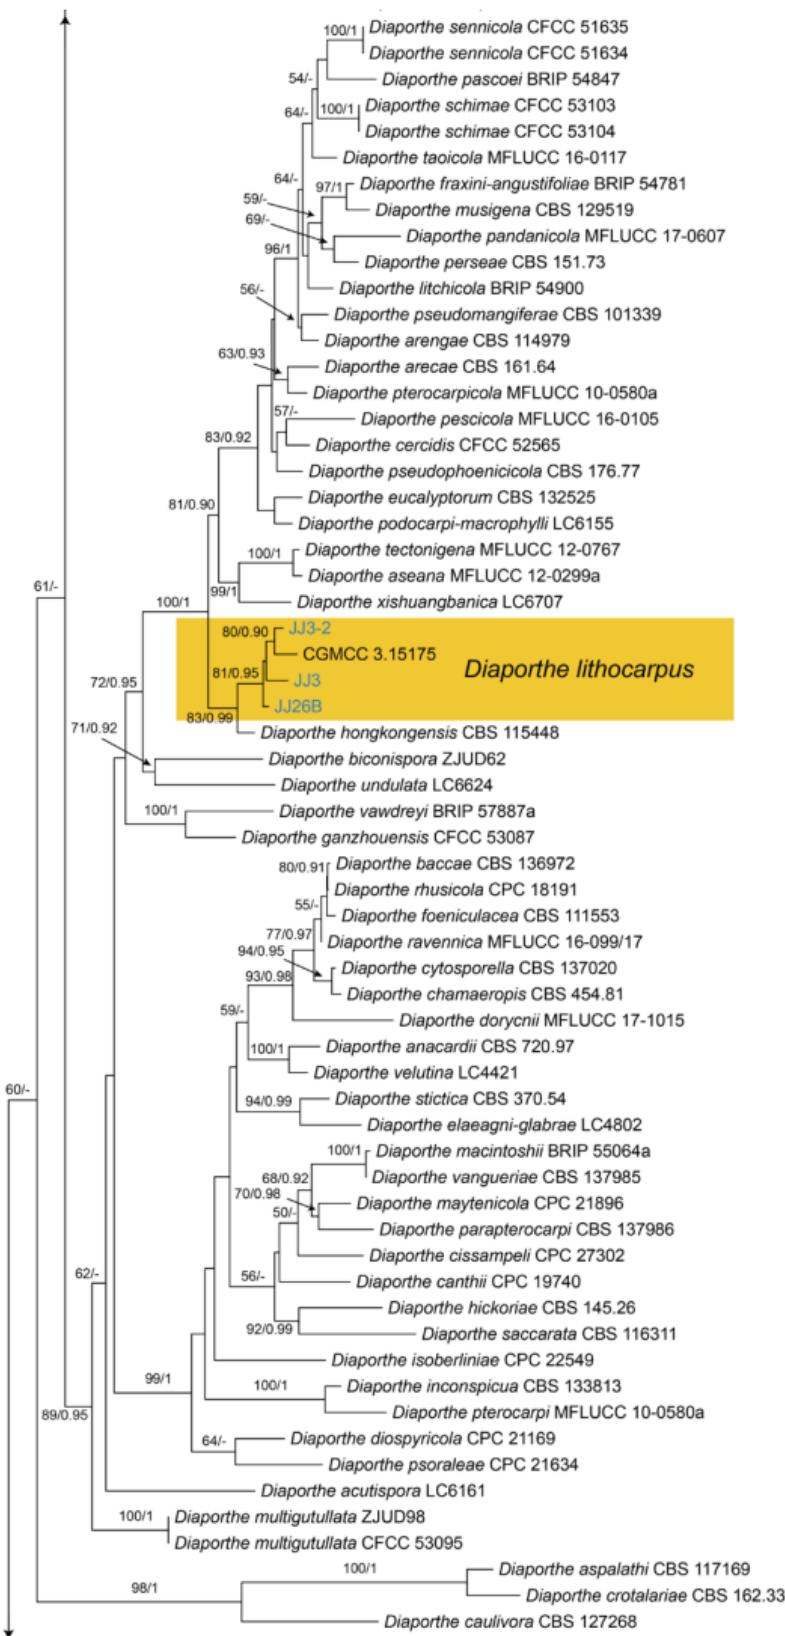

Figure A8. Phylogram generated from RAxML analysis based on combined ITS, LSU, *rpb2*, *tef1* and *tub2* sequence data of *Robillarda* isolates. The tree was rooted to *Strickeria kochii* (CBS 140411). The scale bar indicates 0.04 nucleotide changes per site. Isolates from this study are marked in blue, ex-type strains are marked with *, and the identified species is marked in yellow.

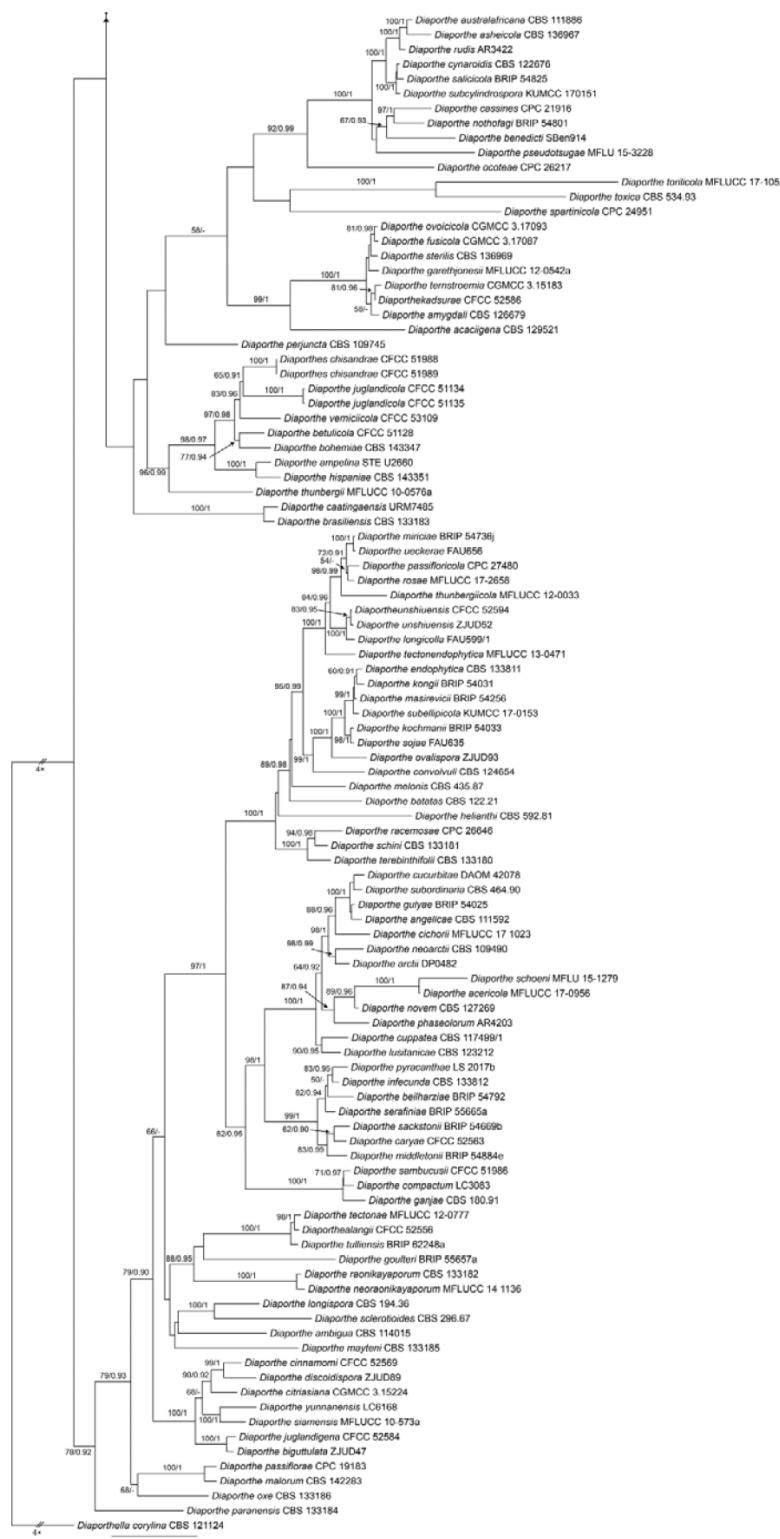

Figure A9. Phylogenetic tree generated from RAxML analysis based on combined ITS, cal, his, tef1 and tub2 sequence data of *Diaporthe* isolates. The tree was rooted to *Diaporthella corylina* (CBS 121124). The scale bar indicates 0.1 nucleotide changes per site. Isolates from this study are marked in blue, and the identified species is marked in yellow.

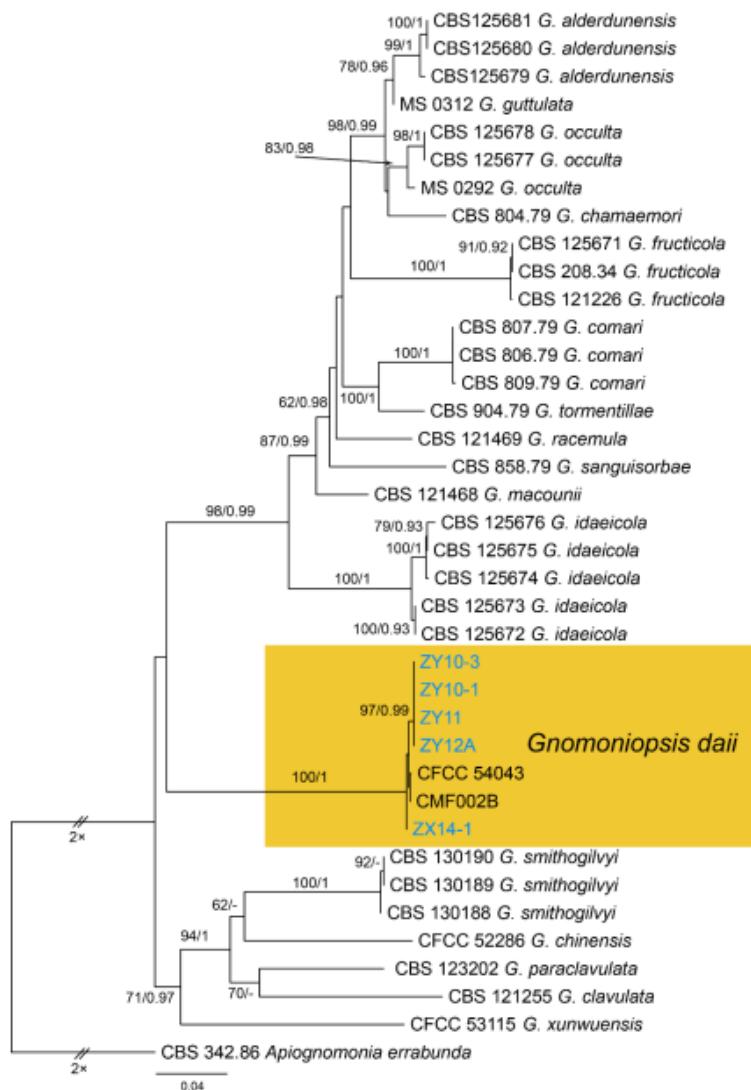

Figure A10. Phylogram generated from RAxML analysis based on combined ITS, *tef1* and *tub2* sequence data of *Gnomoniopsis* isolates. The tree was rooted to *Apiognomonia errabunda* (CBS 342.86). The scale bar indicates 0.04 nucleotide changes per site. Isolates from this study are marked in blue, and the identified species is marked in yellow.

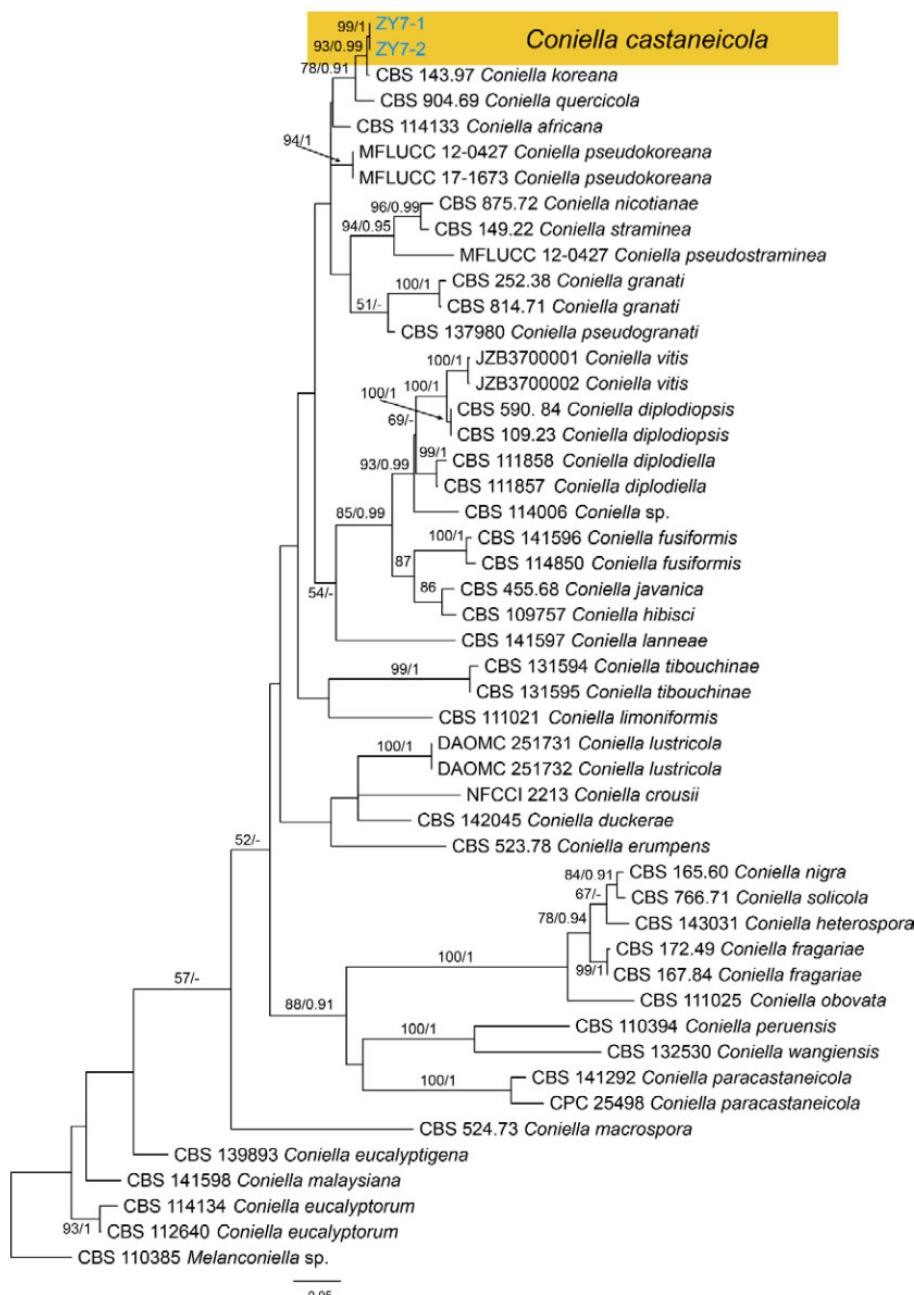

Figure A11. Phylogram generated from RAxML analysis based on combined ITS, *tef1* and *tub2* sequence data of *Coniella* isolates. The tree was rooted to *Melanconiella* sp. (CBS 110385). The scale bar indicates 0.05 nucleotide changes per site. Isolates from this study are marked in blue, and the identified species is marked in yellow.

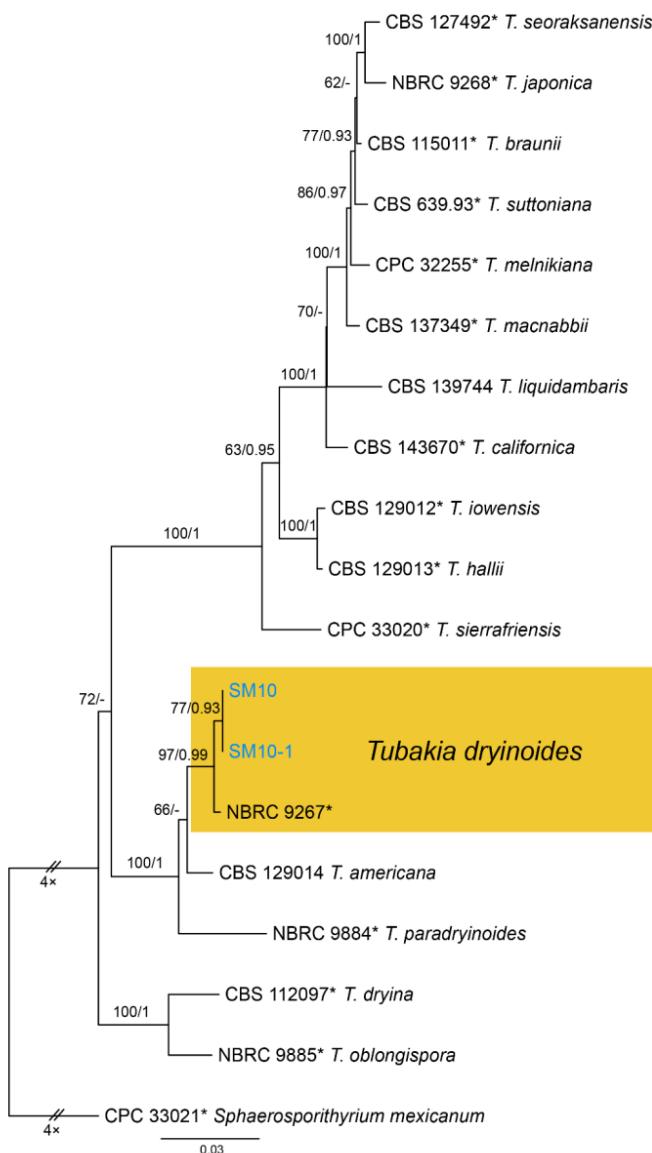

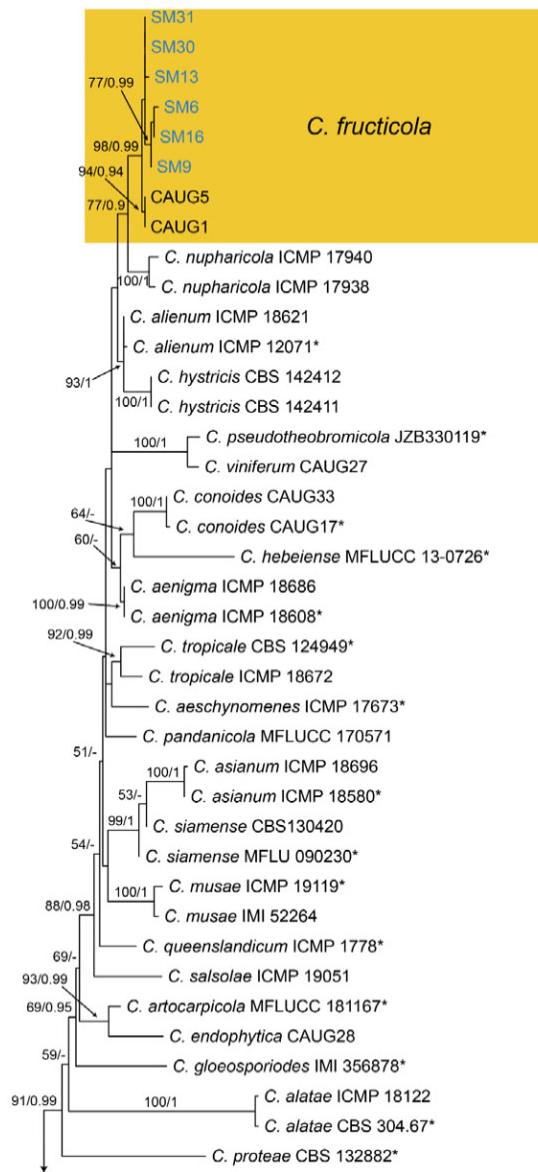

Figure A12. Phylogram generated from RAxML analysis based on combined ITS, *tef1* and *tub2* sequence data of *Tubakia* isolates. The tree was rooted to *Sphaerosporithyrium mexicanum* (CPC 33021). The scale bar indicates 0.03 nucleotide changes per site. Isolates from this study are marked in blue, ex-type strains are marked with *, and the identified species is marked in yellow.

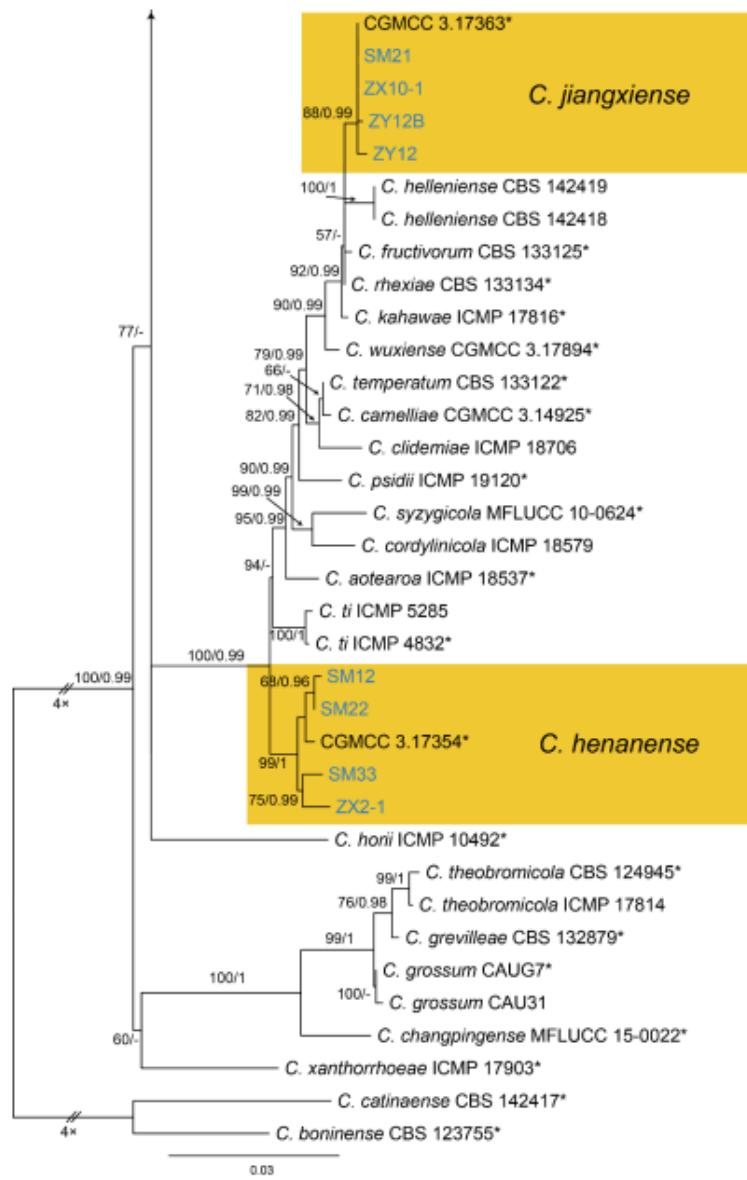

Figure A13. Phylogram generated from RAxML analysis based on combined ITS, *act*, *chs-1*, *gapdh* and *tub2* sequence data of *Collectrichum gloeosporioides* species complex isolates. The tree was rooted to *Collectrichum catinaense* (CBS 142417) and *C. boninense* (CBS 123755). The scale bar indicates 0.03 nucleotide changes per site. Isolates from this study are marked in blue, ex-type strains are marked with *, and the identified species are marked in yellow.

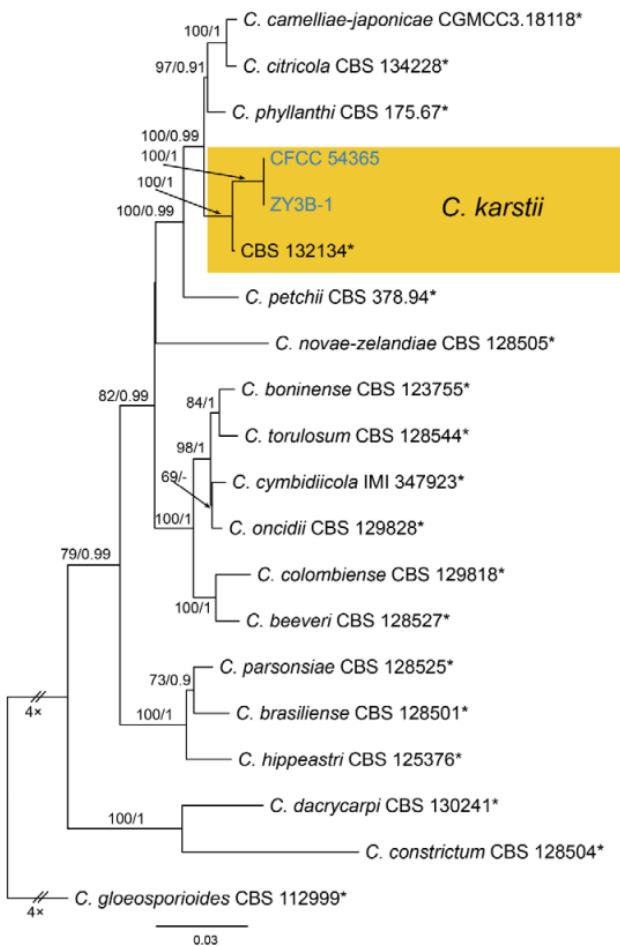

Figure A14. Phylogram generated from RAxML analysis based on combined ITS, *act*, *chs-1*, *gapdh* and *tub2* sequence data of *Collectrichum boninense* species complex isolates. The tree was rooted to *Collectrichum gloeosporioides* (CBS 112999). The scale bar indicates 0.03 nucleotide changes per site. Isolates from this study are marked in blue, ex-type strains are marked with *, and the identified species is marked in yellow.

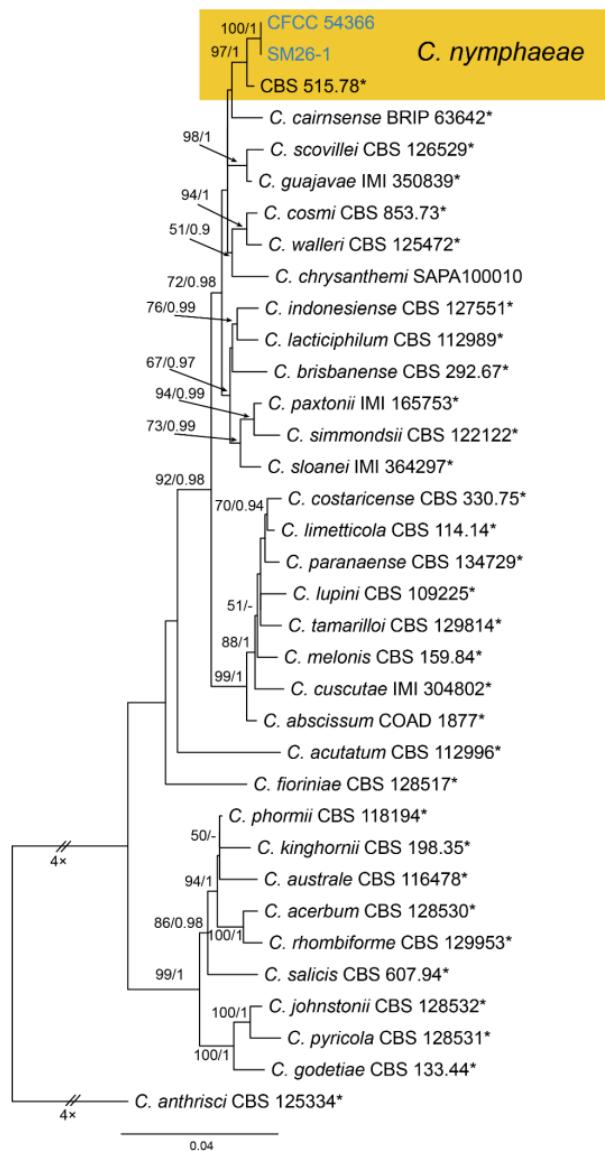

Figure A15. Phylogram generated from RAxML analysis based on combined ITS, *act*, *chs-1*, *gapdh* and *tub2* sequence data of *Collectrichum acutatum* species complex isolates. The tree was rooted to *Collectrichum anthrisci* (CBS 125334). The scale bar indicates 0.04 nucleotide changes per site. Isolates from this study are marked in blue, ex-type strains are marked with *, and the identified species is marked in yellow.
