Abstract: In recent years, structured laser beams for shaping inverse energy flow regions: regions with a direction of energy flow opposite to the propagation direction of a laser beam, have been actively studied. Unfortunately, many structured laser beams generate inverse energy flow regions with dimensions of the order of the wavelength. Moreover, there are significant limitations to the location of these regions. Here, we investigate the possibility of controlling inverse energy flow distributions by using the generalization of well-known cylindrical vector beams with special polarization symmetry—vector Lissajous beams (VLBs)—defined by two polarization orders \((p, q)\). We derive the conditions for the indices \((p, q)\) in order, not only to shape separate isolated regions with a reverse energy flow, but also regions that are infinitely extended along a certain direction in the focal plane. In addition, we show that the maximum intensity curves of the studied VLBs are useful for predicting the properties of focused beams.

Keywords: inverse energy flow; vector Lissajous beams; tight focusing

1. Introduction

It is well-known that structured laser beams with the desired amplitude, phase, and/or polarization distribution are beginning to find more and more applications in various fields of science and technology [1]; many excellent reviews are devoted to the application of such beams in optical communications [2], laser manipulation [3,4], and laser material processing [5], etc. [6]. In recent years, structured laser beams to shape inverse energy flow regions have been actively studied. Inverse energy flow means that the direction of energy flow is opposite to the propagation direction of the beam and is associated with a local change in the sign of the components of the Poynting vector under free propagation [7]. Interest in the investigation of such laser beams is explained by the hope of using such laser beams to pull laser beams that are capable of attracting optically trapped nano- and micro-objects towards a radiation source [8]. If an inverse energy flow is formed on the optical axis, then its presence moves dielectric nanoparticles with absorption in the direction opposite to the propagation of the laser beam, with a greater force than similar particles without absorption. In the absence of an inverse flow, both particles (with and without absorption) move equally [9]. However, just the presence of areas with an inverse energy flow does not guarantee the existence of the attracting optical forces—the gradient-phase force often blocks the effect of the negative Poynting vector component, giving a negative optical force [10,11].

Many different approaches have been used to demonstrate the possibility of shaping inverse energy flow regions—the use of interference patterns generated by four plane waves with linear polarization [12,13], circularly polarized optical vortex (OV) beams [14,15],
cylindrical vector beams (CVBs) [16–19], and OVs with polarization singularities [20]. In all these cases, the dimensions of the region of the formation of the inverse energy flow are small (approximately the order of the wavelength) and the location of this region is limited by the optical axis. Some techniques were proposed to overcome these limitations—the use of annular apertures for the elongation of the area of energy backflow [21,22] and the use of special generalized spiral phase plates to shift the center of the Poynting vector distribution and the maximum negative value of the inverse energy flow from the optical axis [23].

Here, we investigate the possibility of tailoring the inverse energy flow distributions using the generalization of CVBs—vector Lissajous beams (VLBs)—introduced in 2020 [24]. These beams have more degrees of freedom than conventional CVBs—the structure of these beams is defined by two polarization orders \((p, q)\) which can be both integer and fractional. Due to this, VLBs allow one to manage the characteristics of the electromagnetic field, such as the imaginary part of the longitudinal component of the field, the local spin angular momentum (SAM) density, and the complex Poynting vector density [25]. Hao Wu, with co-authors, reported selective trapping of chiral nanoparticles via VLBs due to the use of annular apertures for the elongation of the area of energy backflow [21,22] and the use of special generalized spiral phase plates to shift the center of the Poynting vector distribution and the maximum negative value of the inverse energy flow from the optical axis [23].

Previously, the types of VLBs that can be considered as the generalization of radial polarization, namely \((\cos (pq), \sin (pq))\), have been considered in detail. In this paper, we study a wider set of polarization states related to VLBs: \(x\)- and \(y\)-components of these states can have the same trigonometric dependencies, in particular, \((\cos (pq), \cos (pq))\) and \((\sin (pq), \sin (pq))\). Note that such types of polarizations, even at \(p = q\), do not reduce to known CVBs. This provides new properties of the presented fields. In addition, the possibility of forming a reverse energy flow for focused VLBs has not yet been considered; therefore, such studies are of interest from both fundamental and practical points of view.

2. Theoretical Foundation

The electromagnetic field distribution in a focal domain can be derived by the vectorial diffraction theory [27–36]. The vector nature of radiation should be taken into account when acting on a substance [3–11,37,38], when it propagates in anisotropic or inhomogeneous medium [39–42], and also at tight focusing [27–36]. In the latter case, the calculation of the focused field is often performed using the Debye approximation [27–29,33–36]. For tight focusing using the Debye approximation, the electric and magnetic field vectors are determined as follows:

\[
\begin{bmatrix}
E(\rho, \upsilon, z) \\
H(\rho, \upsilon, z)
\end{bmatrix} = -\frac{i}{\lambda} \int_0^{2\pi} \int_0^{\alpha} F(\theta, \varphi) T(\theta) \begin{bmatrix}
P_E(\theta, \varphi) \\
P_H(\theta, \varphi)
\end{bmatrix} \times \exp[ik(p\sin \theta \cos(\varphi - \upsilon) + z\cos \theta)] \sin \theta \, d\theta \, d\varphi,
\]

where \((\rho, \upsilon, z)\) are the cylindrical coordinates in the focal region, \((\theta, \varphi)\) are the spherical angular coordinates of the focusing system’s output pupil, \(\alpha\) is the maximum value of the azimuthal angle \(\theta\) related to the system’s numerical aperture \(NA = \sin \alpha\), \(k = 2\pi/\lambda\) is the wavenumber, \(\lambda\) is the radiation wavelength, \(f\) is a focal length of an optical system, \(T(\theta)\) is the apodization function; \(F(\theta, \varphi)\) is a complex amplitude of the field at the exit pupil.

The Debye approximation neglects contributions from diffraction at the edge of the aperture, therefore, the correctness of the results is ensured at a high value of the Fresnel number (i.e., when \(f >> \lambda, f\sin \alpha >> \lambda\)), as well as near the focal plane [43–45]. Taking
into account these conditions, expression (1) is a convenient tool for calculating the 3D distribution of the vector field in the focal region [46–48].

Note, in most articles only the electric component of the field is considered. However, to calculate characteristics such as the Poynting vector, expressions for the magnetic component of the field are also required, which can be calculated using Maxwell’s equations. In Equation (1), the polarization transformation vectors for the electric and magnetic field are the following [18,23,25]:

\[
P_E(\theta, \varphi) = \begin{bmatrix} A(\theta, \varphi) & C(\theta, \varphi) \\ C(\theta, \varphi) & B(\theta, \varphi) \end{bmatrix} \begin{pmatrix} c_x(\theta, \varphi) \\ c_y(\theta, \varphi) \end{pmatrix},
\]

\[
P_H(\theta, \varphi) = \begin{bmatrix} -D(\theta, \varphi) & -E(\theta, \varphi) \\ C(\theta, \varphi) & -A(\theta, \varphi) \end{bmatrix} \begin{pmatrix} c_x(\theta, \varphi) \\ c_y(\theta, \varphi) \end{pmatrix},
\]

where

\[
A(\theta, \varphi) = 1 + \cos^2 \varphi(\cos \theta - 1), \quad B(\theta, \varphi) = 1 + \sin^2 \varphi(\cos \theta - 1),
\]

\[
C(\theta, \varphi) = \sin \varphi \cos \varphi(\cos \theta - 1), \quad D(\theta, \varphi) = \cos \varphi \sin \theta, \quad E(\theta, \varphi) = \sin \varphi \sin \theta.
\]

In Equation (2), \( c(\theta, \varphi) = \begin{pmatrix} c_x(\theta, \varphi) \\ c_y(\theta, \varphi) \end{pmatrix} \) is a vector of polarization coefficients of the input field. In [24], the following generalization of cylindrical polarization was considered by introducing two different orders \( (p, q) \) for the x- and y-components, respectively:

\[
c(\varphi) = \begin{pmatrix} \cos(p\varphi + q_x) \\ \sin(q\varphi + q_y) \end{pmatrix}
\]

The polarization state defined by Equation (4) was called the Lissajous polarization [24], since Equation (4) corresponds to the parametric equation of Lissajous figures. Such a figure can be seen in the input field intensity pattern if we draw a curve enveloping the brightest intensity regions.

For the Lissajous polarization defined by Equation (4), one can write the explicit form of the polarization vectors using Equation (2):

\[
P_E(\theta, \varphi) = \begin{pmatrix} \cos(p\varphi + q_x) \cos \varphi + \sin(q\varphi + q_y) \sin \varphi \cos \varphi \cos \theta - & \sin(q\varphi + q_y) \cos \varphi - \cos(p\varphi + q_x) \sin \varphi \sin \varphi \\
- \sin(q\varphi + q_y) \cos \varphi + \cos(p\varphi + q_x) \sin \varphi \sin \varphi & \sin \theta [\cos(p\varphi + q_x) \cos \varphi + \sin(q\varphi + q_y) \sin \varphi] \cos \varphi \cos \theta + \sin \varphi \sin \theta \\
\end{pmatrix}
\]

for \( P_H(\theta, \varphi) \), the corresponding expression will be similar to Equation (5).

If the input field is factorized as follows:

\[
F(\theta, \varphi) = R(\theta) \Phi(\varphi)
\]

then, taking into account the possibility of expanding the function \( \Phi(\varphi) \) in terms of angular harmonics \( \exp(i n \varphi) \), the integrals over the angle \( \varphi \) in Equation (1) are calculated analytically [34]. In this case, Equation (1) is reduced to one-dimensional integrals:

\[
\begin{bmatrix} E(\rho, v, z) \\ H(\rho, v, z) \end{bmatrix} = -\frac{i 2\pi f}{\lambda} \int_0^{\Lambda} R(\theta) T(\theta) \begin{bmatrix} Q_E(\rho, v, \theta) \\ Q_H(\rho, v, \theta) \end{bmatrix} \exp \left( i \frac{2\pi}{\lambda} z \cos \theta \right) \sin \theta \ d\theta,
\]

where vectors \( Q_{E,H}(\rho, v, \theta) \) are superpositions of Bessel functions \( J_n(k \rho \sin \theta) \) and angular harmonics.

In particular,
\[ \mathbf{Q}_E(\rho, \nu, \theta) = \frac{1}{4} \left( \begin{array}{c} 2i^p(1 + \cos \theta)J_p(k\rho \sin \theta) \cos(\nu + \varphi_z) + (1 - \cos \theta) \left[ i^p Bc_2^p + i^p Bc_2^- \right] \sin^2 \theta \\ 2i^q(1 + \cos \theta)J_q(k\rho \sin \theta) \sin(\nu + \varphi_y) - (1 - \cos \theta) \left[ i^q Bc_2^q + i^q Bc_2^- \right] \sin^2 \theta \end{array} \right), \] (8)

where

- \( Bc_1^\pm = J_{n-1}(k\rho \sin \theta) \cos ((n - 1)\nu + \varphi_n) \pm J_{n+1}(k\rho \sin \theta) \cos ((n + 1)\nu + \varphi_n) \),
- \( Bc_2^\pm = J_{n-2}(k\rho \sin \theta) \cos ((n - 2)\nu + \varphi_n) \pm J_{n+2}(k\rho \sin \theta) \cos ((n + 2)\nu + \varphi_n) \),
- \( Bs_2^\pm = J_{n-2}(k\rho \sin \theta) \sin ((n - 2)\nu + \varphi_n) \pm J_{n+2}(k\rho \sin \theta) \sin ((n + 2)\nu + \varphi_n) \).

In Refs. [24,25], special cases of polarization states defined by Equation (4) at \( \varphi_x = \varphi_y = 0 \) were studied. In this paper, we consider a wider set of polarization states defined by Equation (4), when the values of \( \varphi_x, \varphi_y = \{0, \pi/2\} \), i.e., the \( x \)- and \( y \)-components can have the same trigonometric relationships, but with different frequencies \( (p, q) \).

To analyze the characteristics of the energy flow associated with the polarization state defined by Equation (4), it is necessary to calculate the Poynting vector:

\[ \mathbf{S} \propto \mathbf{E}^* \times \mathbf{H} \] (9)

where \( \mathbf{E} \) and \( \mathbf{H} \) are the vectors of the electric and magnetic fields, respectively, calculated using Equation (1) at a fixed value of the parameter \( z \), for example, at \( z = 0 \) (i.e., in the focal plane).

3. Theoretical Analysis

Although several recent works consider all components of the Poynting vector, including the imaginary parts of the transverse components [25,49–51], in this study we will focus on the analysis of only the longitudinal component (in a complex form):

\[ S_z \propto E_x^* H_y - E_y^* H_x = \text{Re}(S_z) + i\text{Im}(S_z) \] (10)

In this case, in the real part of Equation (10), we will be especially interested in the areas of negative values, i.e., reverse flow of energy. Since the longitudinal component of the Poynting vector is determined only by the transverse components of the field defined by Equation (1), we will consider only them in the further analysis.

Note, even if the input field does not depend on the azimuth angle, i.e., \( \Phi(\varphi) = \text{const} \), the components of the polarization vector are composed by angular harmonics \( \exp (in\varphi) \). In this case, it is convenient to represent fields defined by Equation (1) in the focal plane \( (z = 0) \) as a superposition of the following integrals:

\[ I_n^\pm(\rho) = \int_0^\pi R(\theta) T(\theta)|J_n(k\rho \sin \theta)| \sin \theta \, d\theta \] (11)

In Refs. [18,21,23], the field \( R(\theta) \) was considered in combination with a superimposed narrow annular aperture [52]:

\[ D_0(\theta) = \begin{cases} 1, & |\theta - \theta_0| \leq \Delta/2, \\ 0, & \text{else} \end{cases} \] (12)

where \( \Delta \) is the aperture ring width and \( \theta_0 \) is the position of the ring center.

In this case, an increased reverse energy flow area is provided [21]. In addition, integrals defined by Equation (11) take the explicit form:

\[ I_n^\pm(\rho) \propto \Delta \cdot J_n(k\rho \sin \theta_0) T(\theta_0)(1 \pm \cos \theta_0) \sin \theta_0 \] (13)

Let us consider several particular cases of polarization in the form defined by Equation (4).
3.1. Cos-Sin Vector Lissajous Beams (cs-VLBs)

When \( \varphi_x = \varphi_y = 0 \) instead of Equation (4) the result is:

\[
\mathbf{c}(\varphi) = \begin{pmatrix} \cos(p\varphi) \\ \sin(q\varphi) \end{pmatrix}
\]  

Then, the transverse components of the field defined by Equation (1) take the following form (taking into account Equation (11)):

\[
\begin{align*}
\mathbf{E}_x^{cs}(\rho, \nu, 0) &= -\frac{k_f}{4} \times \\
&\times \left( i^{p+1} \begin{bmatrix} 2I_p^+ \cos \rho \nu + I_{p-2}^- \cos(p - 2)\nu + I_{p+2}^- \cos(p + 2)\nu \\
-I^{q+1} \begin{bmatrix} 2I_q^+ \sin \nu \nu - I_{q-2}^- \sin(q - 2)\nu - I_{q+2}^- \sin(q + 2)\nu \end{bmatrix} \right) + i^{q+1} \begin{bmatrix} I_{q-2}^- \cos(q - 2)\nu - I_{q+2}^- \cos(q + 2)\nu \end{bmatrix},
\end{align*}
\]

\[
\begin{align*}
\mathbf{H}_x^{cs}(\rho, \nu, 0) &= -\frac{k_f}{4} \times \\
&\times \left( i^{p+1} \begin{bmatrix} 2I_q^+ \sin q\nu + I_{q-2}^- \sin(q - 2)\nu + I_{q+2}^- \sin(q + 2)\nu \end{bmatrix} - i^{q+1} \begin{bmatrix} I_{p-2}^- \sin(p - 2)\nu - I_{p+2}^- \sin(p + 2)\nu \end{bmatrix} - i^{q+1} \begin{bmatrix} I_{q-2}^- \cos(q - 2)\nu - I_{q+2}^- \cos(q + 2)\nu \end{bmatrix} \right).
\end{align*}
\]  

Based on Equation (15), it can be shown that the longitudinal component consists of two terms:

\[
S_2^{cs} = S_{2x}^{cs} + S_{2z}^{cs}
\]  

where \( S_{2x}^{cs} \) is always real, and the form of \( S_{2z}^{cs} \) depends on the parity of \( p \) and \( q \) values.

Explicitly, the first term is

\[
S_{2x}^{cs} = \frac{1}{4} \left[ \left( I_p^+ \cos \nu \nu \right)^2 + \left( I_q^+ \sin \nu \nu \right)^2 \right] - \frac{1}{10} \left[ \left( I_{p-2}^- \right)^2 + \left( I_{p+2}^- \right)^2 + \left( I_{q-2}^- \right)^2 + \left( I_{q+2}^- \right)^2 \right] - \frac{1}{8} \left[ I_{p-2}^- I_{p+2}^- \cos 2\nu \nu - I_{q-2}^- I_{q+2}^- \cos 2\nu \nu \right].
\]  

To determine the regions of the reverse energy flow, it is necessary to determine the regions of negative values of Equation (17). Obviously, under the condition \( \cos(p\nu) = 0 \) and \( \sin(q\nu) = 0 \), the expression in the first square bracket vanishes. In the third square bracket, this condition is \( \cos(2\nu) = -1 \) and \( \cos(2\nu) = 1 \). Taking into account that the expression in the second square bracket does not depend on the angle, instead of Equation (17) we obtain the following expression for the considered angles:

\[
\nu^{cs}_{inv} \in \{ \cos(p\nu) = 0 \& \sin(q\nu) = 0 \},
\]

\[
S_{2z}^{cs}(\nu^{cs}_{inv}) = - \left[ \left( I_{p-2}^- - I_{p+2}^- \right)^2 + \left( I_{q-2}^- - I_{q+2}^- \right)^2 \right] < 0.
\]

Thus, in the areas corresponding to directions with angles \( \nu^{cs}_{inv} \), the first part of Equation (16) has negative values.

An analysis of the directions for different indices \((p, q)\) is given in Section 4. Note that these directions do not depend on the size of the entrance pupil and, therefore, do not change when a narrow annular aperture is applied.

Let us now consider the second part, which essentially depends on the parity of the indices \((p, q)\). It can be shown that

\[
S_{2z}^{cs} = \begin{cases} 
S_{2z}^{cs, p-q} \, & (p-q) = 4s, \\
S_{2z}^{cs, -p} \, & (p-q) = 4s + 1, \\
S_{2z}^{cs, -q} \, & (p-q) = 4s + 2, \\
-S_{2z}^{cs, p-q} \, & (p-q) = 4s + 3,
\end{cases}
\]  

where
Photonics 2022, 9, 121

\[ S_{z2,e}^\perp = \frac{1}{2} \cos((p + q)v) \left[ I_{p-2}^- I_{q-2}^- - I_{p+2}^- I_{q-2}^- \right] + \frac{1}{8} \cos((p - q)v) \left[ I_{p+2}^- I_{q+2}^- - I_{p-2}^- I_{q+2}^- \right], \]

\[ S_{z2,\rho}^\perp = \frac{1}{2} I_p^+ \cos(pv) \left[ I_{q-2}^- \cos(q - 2)v - I_{q+2}^- \cos(q + 2)v \right] + \frac{1}{4} I_{q-2}^\perp \sin(qv) \left[ I_{p-2}^- \sin(p - 2)v - I_{p+2}^- \sin(p + 2)v \right]. \]

As follows from Equation (19), the longitudinal component of the Poynting vector has an imaginary part \( \text{Im} (S_{z2}^\perp) \neq 0 \) only for an odd index difference \( (p - q) \).

Note that on the directions determined by Equation (18), Equation (19) is equal to zero, i.e., \( S_{z2}^\perp (\nu_{inv}) = 0 \), so the negative values of the real part of the longitudinal component of the Poynting vector are determined only by Equation (18): \( \text{Re} [S_{z2}^\perp (\nu_{inv})] < 0 \).

We note that there is a significant difference between Equation (18) and a similar equation in Ref. [21], where a beam with a linear \( \nu_{inv} \) and a trigonometric amplitude was considered. The expression obtained in Ref. [21] included directions with a zero value of the longitudinal component of the Poynting vector, which did not ensure the connectivity of regions with a reverse energy flow. Under the condition defined in Equation (18), there is a sum of two squares which cannot be equal to zero at the same time for \( (p \neq q) \), therefore, the negative value of the longitudinal component of the Poynting vector and the connectivity of the region of the reverse energy flow along a certain direction are guaranteed.

3.2. Cos-Cos Vector Lissajous Beams (cc-VLBs)

When \( \phi_x = 0 \), \( \phi_y = \pi/2 \) instead of Equation (4), we obtain:

\[ c(\varphi) = \left( \begin{array}{c} \cos(p\varphi) \\ \cos(q\varphi) \end{array} \right) \]  

(20)

Then, the transverse components of the field defined by Equation (1) take the following form:

\[ E_{11}^\perp(\rho, \varphi, 0) = -\frac{kI}{4} \times \]

\[ \left( \begin{array}{c} 2I_p^+ \cos(p\rho) + I_{p-2}^- \cos(p - 2)\rho + I_{p+2}^- \cos(p + 2)\rho \\ 2I_{q-2}^- \cos(q - 2)\rho - I_{q+2}^- \cos(q + 2)\rho \end{array} \right) \]

\[ H_{11}^\perp(\rho, \varphi, 0) = -\frac{kI}{4} \times \]

\[ \left( \begin{array}{c} 2I_p^+ \cos(q\rho) + I_{q-2}^- \cos(q - 2)\rho - I_{q+2}^- \cos(q + 2)\rho \\ 2I_{p-2}^- \cos(p - 2)\rho - I_{p+2}^- \cos(p + 2)\rho \end{array} \right) \]

(21)

As in the previous case, it can be shown that

\[ S_{z1}^\perp = \frac{1}{4} \left[ \left( I_p^+ \cos(p\rho) \right)^2 + \left( I_q^+ \cos(q\rho) \right)^2 \right] - \frac{1}{16} \left[ \left( I_{p-2}^- \right)^2 + \left( I_{p+2}^- \right)^2 + \left( I_{q-2}^- \right)^2 + \left( I_{q+2}^- \right)^2 \right] - \frac{1}{8} \left[ I_{p-2}^- I_{p+2}^- \cos(2p\rho) + I_{q-2}^- I_{q+2}^- \cos(2q\rho) \right]. \]

(22)

Equation (22) takes negative values under the following conditions

\[ v_{inv}^{cc} \in \{ \cos(p\rho) = 0 \& \cos(q\rho) = 0 \}, \]

\[ S_{z1}^\perp (\nu_{inv}^{cc}) = - \left[ \left( I_{p-2}^- - I_{p+2}^- \right)^2 + \left( I_{q-2}^- - I_{q+2}^- \right)^2 \right] < 0. \]

(23)

An analysis of the directions \( v_{inv}^{cc} \) for different indices \( (p, q) \) is given in Section 4.
It can also be shown that

$$S^\text{cc}_{2z} = \begin{cases} S^\text{cc}_{2z,\ell'} (p - q) = 4s, \\
S^\text{cc}_{2z,\rho'} (p - q) = 4s + 1, \\
-S^\text{cc}_{2z,\ell'} (p - q) = 4s + 2, \\
-iS^\text{cc}_{2z,\rho'} (p - q) = 4s + 3, \end{cases} \quad (24)$$

where

$$S^\text{ss}_{2z,\ell'} = -\frac{1}{8} \sin((p + q)v) \left[I_{p-2}^- I_{q+2}^- - I_{p+2}^- I_{q-2}^- \right] + \frac{1}{8} \sin((p - q)v) \left[I_{p+2}^- I_{q+2}^- - I_{p-2}^- I_{q-2}^- \right],$$

$$S^\text{ss}_{2z,\rho'} = \frac{1}{4} I_p^+ \cos(pv) \left[I_{q-2}^- \sin(q-2)v - I_{q+2}^- \sin(q+2)v \right] - \frac{1}{4} I_q^+ \cos(qv) \left[I_{p-2}^- \sin(p-2)v - I_{p+2}^- \sin(p+2)v \right].$$

Similar to the previous case, the longitudinal component of the Poynting vector has an imaginary part \( S^\text{cc}_2 \neq 0 \) only for an odd index difference \( (p - q) \).

Additionally, under conditions defined by Equation (23), Equation (24) is equal to zero, i.e., \( S^\text{ss}_{2z} (v^\text{cc}_\text{inv}) = 0 \), so the negative values of the real part of the longitudinal component of the Poynting vector are determined only by Equation (23): \( \text{Re} [S^\text{cc}_2 (v^\text{cc}_\text{inv})] < 0 \).

### 3.3. Sin-Sin Vector Lissajous Beams (ss-VLBs)

When \( \phi_x = -\pi/2, \phi_y = 0 \) instead of Equation (4) we obtain

$$c(\varphi) = \begin{pmatrix} \sin(pp) \\ \sin(qq) \end{pmatrix} \quad (25)$$

Then, the transverse components of the field defined by Equation (1) take the following form:

$$E^\text{ss}_z(\rho, v, 0) = -\frac{k_f}{4} \times$$

$$\begin{pmatrix} i^{p+1} \left[ 2I_p^+ \sin pv + I_{p-2}^- \sin(p-2)v + I_{p+2}^- \sin(p+2)v \right] + i^{p+1} \left[ I_{q-2}^- \cos(q-2)v - I_{q+2}^- \cos(q+2)v \right] \\ i^{p+1} \left[ 2I_q^+ \sin qv - I_{q-2}^- \sin(q-2)v - I_{q+2}^- \sin(q+2)v \right] + i^{p+1} \left[ I_{p-2}^- \cos(p-2)v - I_{p+2}^- \cos(p+2)v \right] \end{pmatrix},$$

$$H^\text{ss}_z(\rho, v, 0) = -\frac{k_f}{4} \times$$

$$\begin{pmatrix} -i^{p+1} \left[ 2I_q^+ \sin qv + I_{q-2}^- \sin(q-2)v + I_{q+2}^- \sin(q+2)v \right] + i^{p+1} \left[ I_{p-2}^- \cos(p-2)v - I_{p+2}^- \cos(p+2)v \right] \\ i^{p+1} \left[ 2I_p^+ \sin pv - I_{p-2}^- \sin(p-2)v - I_{p+2}^- \sin(p+2)v \right] - i^{p+1} \left[ I_{q-2}^- \cos(q-2)v - I_{q+2}^- \cos(q+2)v \right] \end{pmatrix} \quad (26)$$

In this case

$$S^\text{ss}_{2z} = \frac{1}{4} \left[ (I_p^+ \sin pv)^2 + (I_q^+ \sin qv)^2 \right]$$

$$-\frac{1}{16} \left[ (I_{p-2}^-)^2 + (I_{p+2}^-)^2 + (I_{q-2}^-)^2 + (I_{q+2}^-)^2 \right] + \frac{1}{8} \left[ I_{p-2}^- I_{p+2}^- \cos 2pv + I_{q-2}^- I_{q+2}^- \cos 2qv \right]. \quad (27)$$

Equation (27) takes negative values under the following conditions:

$$v^\text{ss}_\text{inv} \in \{ \sin pv = 0 \& \sin qv = 0 \},$$

$$S^\text{ss}_{2z} (v^\text{ss}_\text{inv}) = - \left[ (I_{p-2}^- - I_{p+2}^-)^2 + (I_{q-2}^- - I_{q+2}^-)^2 \right] < 0. \quad (28)$$

An analysis of directions \( v^\text{ss}_\text{inv} \) for different indices \( (p,q) \) is given in Section 4.

It can also be shown that

$$S^\text{ss}_{2z} = \begin{cases} S^\text{ss}_{2z,\ell'} (p - q) = 4s, \\
S^\text{ss}_{2z,\rho'} (p - q) = 4s + 1, \\
-S^\text{ss}_{2z,\ell'} (p - q) = 4s + 2, \\
-iS^\text{ss}_{2z,\rho'} (p - q) = 4s + 3, \end{cases} \quad (29)$$
where

\[
S^\text{cs}_{z2,p} = \frac{1}{8} \sin((p + q)v) \left[ I_{p-2}^- I_{q+2}^- - I_{p+2}^- I_{q-2}^- \right] + \frac{1}{8} \sin((p - q)v) \left[ I_{p+2}^- I_{q+2}^- - I_{p-2}^- I_{q-2}^- \right],
\]

\[
S^\text{cs}_{z2,q} = -\frac{1}{4} I_p^+ \sin(\nu v) \left[ I_{q-2}^- \cos(q - 2)v - I_{q+2}^- \cos(q + 2)v \right] + \frac{1}{4} I_q^- \sin(qv) \left[ I_{p-2}^- \cos(p - 2)v - I_{p+2}^- \cos(p + 2)v \right].
\]

Thus, the results are similar to the previous cases, i.e., \( \text{Im}(S^\text{cs}_z) \neq 0 \) only for an odd index difference \( (p - q) \). Additionally, under conditions defined by Equation (28), \( S^\text{cs}_{z2}(\nu^\text{typ}) = 0 \), therefore \( \text{Re}(S^\text{cs}_z(\nu^\text{typ})) < 0 \).

It can be seen that although the full expressions for \( S_z \) at the three considered types of VLBs differ, the conditions defined by Equations (18), (23) and (28) for the values \( \text{Re}(S_z) \) in the negative directions are similar. The differences are in the direction angles at which negative values of the real part of the longitudinal component of the Poynting vector are provided, i.e., reverse flow of energy is provided. Therefore, for the same pair of indices \((p,q)\), the number of negative directions is different for the considered types of beams. The differences between the three types of VLBs are discussed in more detail in Section 4.

Note that even if the conditions defined by Equations (18), (23) and (28) are not satisfied, negative values of the longitudinal component are still possible on circles of certain radii, as was considered in Refs. [17,18] for fields with cylindrical polarization. Due to continuity, negative values will not only be on the circles, but also in their neighborhood. Therefore, the overall negative region will have a mesh-cell shape, which was also observed at \( q = 0 \) in Ref. [21].

4. Modeling Results

In this section, the following parameters have been used in modeling for narrow annular aperture, defined by Equation (12): \( \theta_0 = 80^\circ \), \( \Delta = 3.3^\circ \). Obviously, when the ring width \( \Delta \) increase, the total energy in the focal area will increase, but the focusing will become less sharp, and the negative energy flow will decrease [21].

Modeling results contain (see Tables below) the transverse components of electric and magnetic field distributions in the focal plane and distributions of the longitudinal component of the Poynting vector. Moreover, we show the corresponding Lissajous curves (in the first column of Tables):

\[
\begin{align*}
    x &= \cos(p\varphi), \\
    y &= \sin(q\varphi),
\end{align*}
\]

and intensity curves [24] (in the third column of tables):

\[
\begin{align*}
    x &= \left[ \cos^2(p\varphi) + \sin^2(q\varphi) \right]^{1/2} \cos \varphi, \\
    y &= \left[ \cos^2(p\varphi) + \sin^2(q\varphi) \right]^{1/2} \sin \varphi.
\end{align*}
\]

The curve defined by Equation (31) corresponds to the contour of the total intensity distribution in the focal plane. Since the focal intensity is related to the real part of the longitudinal component of the Poynting vector in Equation (10), the intensity curve also corresponds to the structure of \( \text{Re}(S_z) \). By the term “structure” we mean the following: the convex parts of the curve defined by Equation (31) correspond to the locations of maximum positive energy flow, and the concave parts indicate the presence of negative energy flow locations. Infinitely extended regions with \( \text{Re}(S_z) < 0 \) are special cases of our investigation. These are directions satisfying the conditions of Equations (18), (23) and (28). We indicate the infinite (unobstructed) directions (regions) with a negative energy flow by magenta arrows, both for \( \text{Re}(S_z) \) distributions and for intensity curves.

4.1. Cos-Sin Vector Lissajous Beams (cs-VLBs)

It was shown in Refs. [17,18] that the second-order radial polarization \((p,q) = (2,2)\) is optimal from the point of view of maximizing the value of the reverse energy flow on the optical axis. However, the integral characteristic over a region of negative values has been
shown theoretically and numerically [18] to increase with the increasing order of radial or azimuthal polarization \((p = q)\). In this case, the real part of the longitudinal component of the Poynting vector has the following form [18]:

\[
\text{Re} \left[ S_z^{(p)}(p) \right|_{(p,p)} = (\Delta \cdot \pi T(\theta_0) \sin \theta_0)^2 \times \\
\times \left[ 1 + \cos \theta_0 \right] f_p^2(kp \sin \theta_0) - (1 - \cos \theta_0)^2 f_{p-2}^2(kp \sin \theta_0) \right].
\]  

(32)

In this case, the areas with negative values of Equation (32) correspond to a set of concentric rings.

In addition, in Ref. [21], a linearly polarized field was considered, which can be considered a special case of cs-VLBs for \((p, q) = (p, 0)\):

\[
\text{Re} \left[ S_z^{(p)}(p, v) \right|_{(p,0)} = (0.5\Delta \cdot \pi T(\theta_0) \sin \theta_0)^2 \\
\times \left\{ 2 \cos^2(pv) \left[ 1 + \cos \theta_0 \right] f_p^2(kp \sin \theta_0) - \\
- (1 - \cos \theta_0)^2 f_{p-2}^2(kp \sin \theta_0) - f_{p+2}^2(kp \sin \theta_0) \right\}. 
\]  

(33)

For Equation (33), the achievable value of the reverse flow is less than in the case of radial polarization, however, the region of negative values is not limited (in the annular region) since there are directions with negative values of the energy flow.

In Ref. [23], the results for fields that can be considered cs-VLBs and ss-VLBs for \((p, q) = (p, 0)\) were also presented. In addition, the numerical calculation was also made for non-integer \(p\).

The cases considered in this article are more general and may have more unlimited directions of the reverse energy flow.

Tables 1–3 show the calculation results for various indices \((p, q)\). We indicate by magenta arrows the infinite (unobstructed) directions (regions) with a negative energy flow both for Re \(S_z\) distributions and for intensity curves. As seen, the infinite directions present only when the intensity curve passes through the origin (this also follows from Equation (18)), and the number of such directions is equal to the multiplicity of the zero point of the intensity curve.

One can also notice that there are no negative values \(S_z\) in local maxima \(|E_\perp|^2\) or \(|H_\perp|^2\). This follows from Equation (9) (if \(E\) is close to the maximum, then \(H \propto \nabla \times E\) close to zero, and vice versa).

For the case \((p, q) = (2, q)\) (Table 2), one more feature can be noted: if the Lissajous curve is closed, then Im \(S_z^{(p)}\) = 0. For the cases \((p, q) = (1, q)\) (Table 1) and \((p, q) = (3, q)\) (Table 3) there is no such regularity, since all Lissajous curves are closed in these cases.

It can be seen that some distributions are similar up to rotation. This is expected since the polarization functions are trigonometric, but the symmetry properties are quite diverse and difficult to predict from the curve patterns. For example, for \((\cos \varphi, \sin 3\varphi)\) (Table 1) and \((\cos 3\varphi, \sin \varphi)\) (Table 3) Lissajous curves and intensity curves are the same for rotation, but the field distributions and \(S_z\) are qualitatively different. At the same time, for \((\cos 2\varphi, \sin 3\varphi)\) (Table 2) and for \((\cos 3\varphi, \sin 2\varphi)\) (Table 3), the corresponding curves have no similarity at all. This is probably due to the evenness of the indices \((p, q)\).
Table 1. Calculation results for cs-VLBs in the focal plane in the case $(p, q) = (1, q)$: $|E^x|^2$, $|H^z|^2$ (red color for $x$-components and green color for $y$-components), and $S_2^{cs}$ (gray color for positive values and magenta color for negative values).

Table 3. Calculation results for cs-VLBs in the focal plane in the case \( (p, q) = (3, q) \).

| Polarization State \( c(\varphi) \), Lissajous Curve | \( |E^c_x|^2 \) and \( |H^c_x|^2 \) in the Focal Plane | Intensity Curve | \( \text{Re}(S^c_x) \) and \( \text{Im}(S^c_x) \) in the Focal Plane |
|-------------------------------------------------|--------------------------------------------------|-----------------|---------------------------------|
| \((\cos 3\varphi, \sin \varphi)\)                   | ![Image 1](image1.png)                           | ![Image 2](image2.png) | ![Image 3](image3.png)          |
| \((\cos 3\varphi, \sin 2\varphi)\)                | ![Image 4](image4.png)                           | ![Image 5](image5.png) | ![Image 6](image6.png)          |
| \((\cos 3\varphi, \sin 3\varphi)\)               | ![Image 7](image7.png)                           | ![Image 8](image8.png) | ![Image 9](image9.png)          |
| \((\cos 3\varphi, \sin 4\varphi)\)               | ![Image 10](image10.png)                         | ![Image 11](image11.png) | ![Image 12](image12.png)        |
| \((\cos 3\varphi, \sin 5\varphi)\)               | ![Image 13](image13.png)                         | ![Image 14](image14.png) | ![Image 15](image15.png)        |

Let us also note the case \((\cos 3\varphi, \sin 5\varphi)\) (Table 3). It appears visually from the \( \text{Re}(S_z) \) distribution that the diagonal directions are the infinite regions with a negative energy flow. However, in the central part there is a slight interruption of the line with negative \( \text{Re}(S_z) \). For \((\cos 3\varphi, \sin 5\varphi)\), the condition of Equation (18) is not met, and the intensity curve do not pass through the origin. So, this is a good example demonstrating the effective visibility of the intensity curve to determine the presence of the infinite regions with a negative energy flow.

4.2. Cos-Cos Vector Lissajous Beams (cc-VLBs)

It can be seen that the structure of the cs-VLBs and cc-VLBs fields for the same indices \((p, q)\) is noticeably different. This provides a variety of generated distributions, even for small indices. In some cases, for example, for \((\cos \varphi, \cos 2\varphi)\) (Table 4) and for \((\cos 2\varphi, \cos \varphi)\) (Table 5), the differences are reduced to the rotation of the Lissajous curve and the permutation of the distributions for \( \mathbf{E} \) and \( \mathbf{H} \), which is expected when permuting the polarization functions of the same name.
Table 4. Calculation results for cc-VLBs in the focal plane in the case \((p, q) = (1, q)\).

</tbody>
</table>

Note that in the field distributions in the first row of Table 4, the direction along which the maxima are placed has an angle lower than 45 degrees horizontally, although the initial polarization is diagonal. This is a sharp focusing effect that should disappear in a paraxial situation.

In Tables 4 and 5, all Lissajous curves are open.

4.3. Sin-Sin Vector Lissajous Beams (ss-VLBs)

For this type of VLBs, some of the distributions are similar to the previous cases and some of the distributions are different. A feature of this type is the presence of infinite directions with a reverse energy flow for arbitrary indices \((p, q)\).
As can be seen from the modeling results for ss-VLBs with indices \((1, q)\) (Table 6), there is always one horizontal direction \(v_{inv}^{ss} = 0^\circ\) with a reverse energy flow. Note that in this case, if the Lissajous curve is not closed, then \(\text{Im} (S_z) = 0\), i.e., the opposite situation is observed for cs-VLBs with indices \((2, q)\) (Table 2).

For ss-VLBs with indices \((2, q)\) (Table 7), there is always one horizontal direction \(v_{inv}^{ss} = 0^\circ\) or two diagonal directions \(v_{inv}^{ss} = 45^\circ, 135^\circ\) with a reverse energy flow, depending on the parity of the indices \((p, q)\).

Table 8 shows the modeling results, clearly illustrating the differences between the three types of VLBs for the same indices \((p, q)\). As can be seen, similar (up to rotation) distributions can be observed for different types, depending on the parity of the indices. However, some distributions cannot be obtained by rotation.

Note, as the indices \((p, q)\) increase, the total area with inverse energy flow increases, although infinitely extended directions may be absent.

5. Discussion

As follows from the theoretical analysis and the results of numerical modeling, with the same pair of indices $(p, q)$, the number of directions with a negative energy flow are different in the three considered cases. We pay special attention to these directions, since it is their appearance that provides an advantage in the distribution of the reverse energy flow for the considered types of VLBs over CVBs [16–19], circularly polarized vortex beams [14,15], and also linearly polarized beams with trigonometric amplitude [21,23].

As shown by the results of the numerical simulation given in Section 4, the intensity curves defined by Equation (31) are very useful for predicting the properties of focused beams: 1) the number of infinite directions is equal to a multiple of the zero point of this curve, 2) the convex parts of the curve correspond to the locations of maximum positive energy flow, and the concave parts indicate the directions for the presence of negative energy flow locations. Directions passing through the center (without crossing the intensity curve) correspond to the infinite directions of negative energy flow. These are the directions (indicated by magenta arrows) that satisfy the conditions defined by Equations (18), (23) and (28) and correspond to the infinite directions of negative energy flow.

Below, we provide tables with the numbers of such directions in the range $\{0; \pi\}$ for $(p, q) \leq 10$. The direction angles in the range $[\pi; 2\pi]$ are obtained by simply adding $\pi$ to each angle in the range $[0; \pi]$.

For type cs-VLBs, angles with directions $\alpha_{cs}^{pq}$ are determined from Equation (18). This case is the most difficult to analyze, since it is necessary to take into account not only the parity of the indices but also their multiplicity:

1. If $q = p$, then there are no directions,
2. If $q$ is odd, then there are no directions,
3. If $q$ and $p$ are even, but $q / 2$ is odd, then there are no directions,
4. If $q$ is even and $p = 1$, then there is one direction,
5. If $q$ is even and $p = q / 2$, then there are $p$ directions,
6. If $q$ is even and $p$ is a multiple of $q / 2$, then there is at least one direction.

The listed rules do not cover all possible cases, therefore, to fill in Table 9, sometimes it is required to explicitly calculate the roots of the equations $\cos p\varphi = 0$ and $\sin q\varphi = 0$. In total, 49 directions were obtained for the considered set of indices (Table 9). Note that the matrix is not symmetric, and there are no negative directions on the diagonal ($p = q$ corresponds to CVBs).

The methods for calculating the number of directions for the types cc-VLBs and ss-VLBs are much simpler and are based on the use of the greatest common divisor (GCD). For cc-VLBs, the number of directions is calculated as follows: denote GCD of \((p,q)\) as \(L\); if the numbers \(p/L\) and \(q/L\) are of different parity, then there are no directions, otherwise, the number of directions is equal to \(L\).

For the considered set of indices, there are only 91 possibilities (Table 10), and a significant number of them (it equals to 55) are situated on the diagonal \((p = q)\) corresponds to linear polarization). The matrix is symmetrical.

</table>

For ss-VLBs, the number of directions is equal to \(L\), i.e., GCD of \((p,q)\). In this case, for the considered set of indices, the largest number of negative directions is 189 (Table 11). The matrix is symmetrical, there is the same number of directions as for cc-VLBs (it equals to 55) on the diagonal \((p = q)\) corresponds to linear polarization).

The diagonals are discussed separately, since it corresponds to beams that are degenerate Lissajous beams, which were considered earlier: for cs-VLBs, these are beams with \(p\)-th order radial polarization \([18]\); for cc-VLBs and ss-VLBs, these are beams with linear diagonal polarization, which do not qualitatively differ from beams with linear \(x\)-polarization \([21,23]\).

Thus, ceteris paribus, the ss-VLBs type provides, on average, the largest area of the negative energy flow region.

6. Conclusions

The study of the possibility of forming a reverse energy flow for various types of VLBs showed the effectiveness of this type of polarization for a given characteristic of a focused field. The conditions for the indices \((p, q)\) for the considered types of VLBs were obtained, under which the formation of not only separate isolated regions with a reverse energy flow but also entire directions were provided. In this case, the formed region was infinitely extended along a certain direction in the focal plane.

Numerical simulations have shown that intensity curves are useful for effectively predicting the properties of focused beams: the presence of infinite connected directions with negative energy flow is guaranteed when the intensity curve passes through the origin, and the number of such directions is equal to a multiple of the zero point of the intensity curve. Moreover, the convex parts of the intensity curve correspond to the locations of maximum positive energy flow, and the concave parts indicate the directions for the presence of negative energy flow locations. Directions passing through the center (without crossing the intensity curve) correspond to the infinite directions of negative energy flow.

Although some of the generated distributions are similar for different types of VLBs, even for small values of the indices \((p, q)\), a significant variety of energy flow distributions is provided, which is convenient for practical implementation, since high-frequency distributions require a higher resolution of optical elements.

A feature of ss-VLBs is the presence of infinite directions with a reverse energy flow for arbitrary indices \((p, q)\). In this case, the largest number of such directions is formed, which, providing others are equal, provides the largest area of the negative energy flow region. The results of numerical studies fully confirm this.

Thus, the variety of optical fields with negative energy flow generated by VLBs is useful for controlling light on a nano- and microscale to form a given distribution of forces acting on optically trapped particles.
